## DRUG THERAPY IN CORONARY DISEASE

HARRY GOLD, M D  
NEW YORK

The use of drugs in coronary disease resolves itself into the treatment of several symptoms and functional disorders of the heart and circulation. There are at present no chemical agents that can materially influence directly the course of the structural abnormality in the heart muscle and its blood vessels. Therefore, drugs have no place in the treatment of coronary disease if the subject is free of symptoms or of manifest disorders of function. The one exception is cardiovascular syphilis with coronary involvement.

The chief specific objectives toward which drug therapy is directed in the course of coronary disease are (1) pain, (2) nervous symptoms, apprehension, anxiety and restlessness, (3) congestive heart failure, (4) paroxysmal dyspnea, (5) shock, and (6) disorders of heart rhythm (auricular fibrillation or flutter, ventricular tachycardia).

The agents most frequently employed in connection with one or another of these phenomena are (1) nitrites, (2) xanthines (theobromine and theophylline), (3) sedatives, (4) opium alkaloids, (5) digitalis, (6) quinidine, (7) diuretics, (8) oxygen, (9) papaverine, (10) iodides, (11) tissue extracts and (12) emergency measures.

The use of these drugs is not confined to the treatment of coronary artery disease, but I wish to restrict my remarks chiefly to those matters concerning their use which have to do more particularly with problems arising in coronary disease.

### THE NITRITES

The nitrites are the drugs of choice in the treatment of the pain of effort angina. Attention to certain details will materially enhance their usefulness. These agents dilate all the peripheral arterioles, including the coronary vessels. The ensuing readjustment of the circulation provides a more favorable relationship between cardiac work and coronary flow. This is a physiologic form of relief, since the nitrites do not impair perception of pain but abolish the mechanism that causes the pain. The nitrites are not entirely free of disagreeable effects: the flush, headache, sensation of throbbing and tension in the head, palpitation and, in excessive doses, collapse. The patient should be

warned about the minor symptoms to avoid alarm. Sometimes these symptoms can be obviated by reducing the dose without appreciable loss of the cardiac effect.

The dose should be taken at the first suggestion of the oncoming pain rather than to wait for its full development, as patients often do, guided by a mistaken notion that some danger of injury or habit is involved in frequent use of the nitrites. Patients often declare that they endure the pain as long as they can before taking a tablet in order to avoid taking too many. It is desirable to instruct them that if the first dose does not relieve the pain within five minutes they may repeat it as many times as necessary at intervals of five minutes, until either the pain subsides or sufficient headache appears to preclude its further use for that attack. They should understand that in the doses recommended the drug is practically harmless and that as many as fifty tablets or more of glyceryl trinitrate may be taken a day without fear of injury.

For a patient with extremely frequent attacks of pain, ten or fifteen a day, coming on with the slightest provocation, even while the patient is at rest, the use of a tablet or two of glyceryl trinitrate regularly at intervals of about two hours, irrespective of whether pain is present or not, will often considerably reduce the number of attacks or even abolish them. These are sometimes desperate cases and no end of suffering may be prevented by this prophylactic measure. The danger which has been suggested that the prevention of attacks removes an important protective signal is not significant, since these patients soon discover that only during the most rigorous control of their mental and physical stress will this prophylactic dose of nitrite prove effective.

The question of habituation is sometimes raised. It takes two forms: 1. Will the frequent use of the nitrites in the course of time lead to dependence on them? 2. Will their frequent use reduce their efficacy? The patient may be assured that neither of these consequences will occur. A form of acquired immunity to the nitrites exists. It is seen in nitrite factories. The workers develop severe headaches, which subside after exposure for three or four days. This form of tolerance so rapidly disappears, however, that if the worker takes a vacation for a few days it is the practice to place glyceryl trinitrate in the hat bands during this time in order to retain the tolerance.<sup>1</sup> Such tolerance to the cardiac effect is quite exceptional, if it occurs at all, in the use of the small doses necessary in the treatment of effort angina, although with advancing disease larger doses often become necessary. I have been tempted to try the experiment of placing some glyceryl trinitrate in the hat band of the patient sub-

Read before the Section of Medicine of the New York Academy of Medicine Oct. 18 1938. Paper prepared in collaboration with Dr N T Kwit.

ject to innumerable attacks of effort angina to provide more or less constant exposure to this drug

There is a phenomenon in patients with effort angina which has the appearance of an acquired tolerance. If a patient who has been securing satisfactory relief in the attacks of effort angina by means of the nitrites reports that he has had an attack of pain in which the usual relief was no longer obtained, he may have suffered an attack of coronary thrombosis. In most instances the severity of the attack will itself be sufficiently dramatic to direct attention to the fact that a coronary vessel has become occluded, but not infrequently this is not the case, and failure to obtain the usual relief by the nitrites is all there is in the history that distinguishes the mild attack of coronary thrombosis from the patient's previous attacks of angina pectoris. An electrocardiogram at this time is likely to prove of great value.

In the pain of the acute phase of coronary thrombosis the nitrites only occasionally afford relief. In those cases in which the arterial pressure remains high during the early days and recurring attacks of pain take place, the nitrites prove helpful. The pain in some of these cases appears to arise from two sources: (1) the completely infarcted area from which the impulses are likely to disappear after a few hours and (2) the adjacent muscle with impaired circulation, which was only partly dependent on the occluded vessel. This pain may recur during several days and appears to be similar in its behavior to that of effort angina. It is relieved by nitrites.

There is some hazard in the use of nitrites in the acute phase of coronary thrombosis, because the nitrites reflexly (from fall of blood pressure) stimulate the cardiac accelerators, which may precipitate dangerous ectopic tachycardias, and, by further lowering the blood pressure, which may already have fallen considerably, it may impair the blood flow to the rest of the coronary bed, since the efficiency of the coronary circulation depends on an adequate level of systemic pressure.

All the nitrites act qualitatively alike, and if suitable doses of one have been given without relief it is not likely that any other member will prove any more effective. The most satisfactory preparation is the tablet triturate of glyceryl trinitrate, and the average dose is  $\frac{1}{150}$  grain (0.0004 Gm) dissolved under the tongue. The pearl of amyl nitrite is commonly used by inhalation. On the whole it is not as satisfactory as the tablet of glyceryl trinitrate, with which the exact dose can be more accurately determined. In the case of amyl nitrite, the amount actually inhaled varies greatly. Furthermore, the drug is absorbed from the lungs more rapidly than glyceryl trinitrate from the sublingual tissues, producing more violent effects, and the dose of 5 minims (0.3 cc) in a pearl sometimes causes alarming symptoms in patients who are too careful to allow little or none of it to escape. Levy<sup>2</sup> recommends erythrol tetranitrate in a dose of one-half grain (0.03 Gm) at bedtime to control attacks of pain which are likely to occur during the night.

An interesting contribution to the subject of nitrite therapy was recently published by Krantz and his collaborators<sup>3</sup> from the University of Maryland. They

prepared several alkyl nitrites in the hope of combining a vasodilator action with a central sedative action of the type produced by trichloroethylene. One of the resulting compounds, octyl nitrite, appears to offer distinct advantages. It is a volatile substance supplied on saturated pledgets of cotton in a convenient glass tube inhaler similar to the familiar pocket devices employed for the treatment of nasal catarrh. Their results show that it is less potent than amyl nitrite and less volatile, that for a given degree of vasodilatation the nitrite content of the blood is lower after this compound than after amyl nitrite, that there is less methemoglobin formed and that its duration of action is considerably longer. Octyl nitrite is still in the experimental stage, but the indications are that it may have a useful place in the treatment of effort angina.

#### XANTHINES

The purine bases, particularly theobromine and theophylline, are extensively employed in the treatment of coronary artery disease. These agents are not soluble in water but, when mixed with ethylenediamine or certain salts such as sodium acetate or sodium salicylate, they go into solution readily. They are more widely used in the form of these double salts. One of the most popular of this type of preparation is theophylline with ethylenediamine, or aminophylline.

It was in 1895 that attention was first directed to the use of the xanthines in angina pectoris.<sup>4</sup> In the period of forty years that has elapsed their use for this purpose has gained momentum, and at the present time it is probable that few sufferers with cardiac pain escape a course of treatment with aminophylline at one time or another. With only one exception, clinical reports have considered these compounds effective in controlling the pain of angina pectoris. In 1902 a German writer<sup>5</sup> declared their introduction to be "the most praiseworthy achievement of the last decade," and in 1929 a paper<sup>6</sup> appeared in this country in which the writers stated that they concurred in this view with "equal emphasis." My associates and I were not at all impressed with the results we obtained with these compounds in isolated observations. On inquiry among prominent clinicians we learned, furthermore, that there exists a very considerable body of unpublished testimony to the effect that the xanthines are of questionable value in the relief of cardiac pain. An analysis of the favorable published clinical reports showed also that the conclusions were, without exception, based on observations lacking in suitable control. A few years ago this question was reexamined in our clinics in 100 selected cases of effort angina. It is not feasible to discuss here the manner in which the study was carried through further than to say that techniques were devised for controlling numerous sources of error encountered in the study of the effects of drugs on cardiac pain, such as emotional factors, the diet, the condition of the bowels, physical effort, changes in weather, spontaneous fluctuations in the functional state of the coronary circulation and subconscious bias of the examiner. How this was done is described in detail in a paper published a year ago.<sup>7</sup> The results of that study showed that

patients with coronary artery disease and effort angina obtain no more relief from their cardiac pain from these compounds than they do from sugar of milk administered in the same way.

We had about made up our minds that the xanthines deserve no place in the treatment of cardiac pain when an experimental study was published by Smith and his collaborators<sup>8</sup> which appeared to indicate that large doses of aminophylline greatly reduce the size of the resulting scar after a coronary artery was ligated. These results supplied experimental support for their practice of giving large doses of aminophylline to patients with coronary thrombosis. If that observation could be confirmed, it goes without saying that it would represent a discovery of surpassing significance. The conclusion was based on a small number of animal experiments, and the sizes of the scars were not measured but were estimated. The matter was reinvestigated in our laboratory.<sup>9</sup> Larger numbers of animals were used and the sizes of the infarcts were accurately measured by means of a planimeter. An important source of error was eliminated by the use of the "blind test." Unfortunately the results could not be confirmed. In fact, our "treated" animals turned out to have on the average larger infarcts than the "untreated" ones, even though the same vessel was ligated at the same point in the "treated" and "untreated" series.

The evidence, therefore, leaves no escape from the conclusion that aminophylline, theocaine, theobromine with sodium salicylate, or any of the other xanthine compounds exerts no action that is useful for the routine treatment of cardiac pain or myocardial infarction. I do not wish to be understood as believing that the purine bases have no use at all in cardiac disorders. On the contrary, they are extremely valuable as diuretics in congestive cardiac failure. Also respiratory depression with Cheyne-Stokes respiration occurring in the course of renal or cardiac failure often shows dramatic improvement from the intravenous injection of from 0.25 to 0.5 Gm of aminophylline.

#### MORPHINE

In the classic case of coronary thrombosis in which there is agonizing pain, anguish and terror of impending death, morphine is the drug of choice. The relief of the pain is due to raising the threshold at the center and not to dilatation of coronary arteries, since morphine causes constriction of smooth muscle and, by its vagal stimulating action, also tends to constrict the coronary bed. It owes its beneficial effects not only to the fact that it relieves pain but to the fact that it abolishes a disposition to move about and in many instances gives rise to a sense of well-being which is quite apart from its analgesic effects, the euphoria characteristic of this narcotic.

It may be noted that in some cases the pain is so severe that even morphine is not entirely effectual. In these instances the most one succeeds in doing by safe amounts is to dull the sharp edge of the pain by repeated doses, and after a period of several hours the pain subsides, partly as the result of its natural course independent of the drug. One should not attempt to

abolish the pain completely in such cases, since doses sufficient to do this will produce dangerous depression of the respiration.

Morphine sometimes complicates the course of coronary thrombosis. It promotes constipation with abdominal distention and urinary retention through spasm of the bladder sphincter. It also causes vomiting, which may be repeated over a period of several hours. This violent muscular effort is a source of danger in coronary thrombosis. It is also a source of confusion in that one may be at a loss to determine whether the vomiting is due to the drug or to the coronary thrombosis itself. Morphine causes strong vagal stimulation, and this renders the heart more susceptible to ventricular ectopic rhythms. One may well ask how often ventricular tachycardia after coronary thrombosis is due in part at least to the morphine with which the condition was treated. Morphine poisoning is more likely to occur in cases in which large doses of the drug appear to be necessary for the relief of agonizing pain if the pain subsides spontaneously before any appreciable amount of the drug has been excreted. This applies particularly to cases of coronary thrombosis, for in them occasionally even excruciating pain may subside spontaneously within about one-half hour. When such a patient has received a grain of morphine, the disappearance of the pain is occasionally followed by rather pronounced stupor with profound depression of respiration at 3 or 4 a minute because the stimulant effect of the pain has disappeared. Older patients are more sensitive to this phenomenon.

Two facts concerning morphine have received great emphasis, and deservedly so, in clinical writings on its use in coronary thrombosis: (1) that large doses are necessary and (2) that these patients are very tolerant to morphine. The reasons for these are important. Large doses are needed because the pain is so severe, and the patient appears tolerant because pain is an antidote to morphine poisoning. To be aware of these reasons is perhaps more necessary now than ever before, because of the advances that have been made in recent years in the recognition of the milder cases. The classic picture is often missing in patients now readily recognized as having coronary thrombosis. In them the pain is not excruciating, it is of relatively short duration, and the fear of impending death is absent.

A plan which is applicable in the majority of cases is this: one-fourth grain (0.016 Gm) of morphine sulfate by subcutaneous injection, repeated at intervals of one-half hour until the pain is abolished or reduced to a minimum. The interval between doses should not be shorter, and to give more than a total of 1 grain (0.065 Gm) in twelve hours is rarely wise. Larger doses than 1 grain are rarely more effectual against the pain.

In 1932 an eminent author<sup>10</sup> wrote: "During the acute attack relief of pain can only be accomplished, and even then only too slowly, by giving one-half grain of morphine hypodermically and repeating as necessary. Other substitutes for this drug are worthless and smaller doses do no good." This advice seems much too drastic for the conditions that prevail at the present time. One should not discourage the use of large doses of morphine in cases of coronary thrombosis in which they are essential, but the problem does need to be viewed somewhat more broadly. Not all patients

<sup>8</sup> Fowler W. M., Hurevitz H. M. and Smith F. M. Effect of Theophylline with Ethylenediamine on Experimentally Induced Cardiac Infarction in the Dog. *Arch. Int. Med.* 56: 1242 (Dec.) 1935.

<sup>9</sup> Gold Harry, Travell Janet and Modell Walter. The Effect of Theophylline with Ethylenediamine (Aminophylline) on the Course of Cardiac Infarction Following Experimental Coronary Occlusion. *Am. Heart J.* 14: 284 (Sept.) 1937.

<sup>10</sup> Paulin J. E. Coronary Thrombosis in Modern Concept of Cardiovascular Disease Vol. 1 October 1932.

with coronary thrombosis require large doses of morphine, and many of them require no morphine at all. One not infrequently encounters patients with coronary thrombosis who receive morphine two or three times a day in a routine manner although the subjective symptoms due to the disease are almost negligible. As already mentioned, this drug often complicates the course of the disease and is not infrequently the cause of its most troublesome symptoms, namely, abdominal distention, urinary retention, vomiting, irregular heart, stupor and respiratory depression. The vague notion is entertained that morphine exerts a direct beneficial effect in coronary thrombosis independent of its influence on symptoms. There is no sound justification for this view. Severe pain, its attending anxiety and the distress of paroxysmal dyspnea are the three major indications for the use of morphine in the course of coronary thrombosis. In the absence of these the occasion is rare indeed when the use of morphine is justified.

As for substitutes for morphine, codeine in doses of one-half grain or 1 grain may often be used with advantage in the milder cases of coronary thrombosis. If moderate pain persists over several days, the danger of disagreeable withdrawal symptoms is greatly minimized by the substitution of codeine, even though morphine may have been used during the early pain of the greater severity. Dilaudid, one of the synthetic derivatives of morphine, is about five times as potent and may be used in place of morphine in about one-fifth the dose, about  $\frac{1}{20}$  grain (0.003 Gm.) of dilaudid therefore being given in cases in which one-fourth grain of morphine might otherwise be used. It is doubtful whether it has any advantages over morphine in this disease. It must be used as cautiously as morphine in view of the likelihood that it also is habit forming. Opium contains about twenty different alkaloids, and the view has gained currency that the total alkaloids of opium have special merits in coronary thrombosis. A preparation known as pantopon is widely used for that purpose. There is no satisfactory pharmacologic or clinical evidence that this preparation exerts any effects other than those due to the morphine it contains.<sup>11</sup> If by any chance the patient is intolerant to morphine, so that ordinary doses cause vomiting or excitement, a combination in a capsule of one-half grain or 1 grain of codeine with  $\frac{1}{150}$  grain of scopolamine hydrobromide will occasionally provide a satisfactory substitute.

In cases in which there is pain that is resistant to other measures, placing the patient in a tent with oxygen of about 50 per cent concentration is sometimes useful.<sup>12</sup> It is especially applicable in those presenting cyanosis.

#### THE BARBITURATES

Sedatives play an important role in the management of patients with coronary disease. The most popular ones at the present time are members of the barbituric acid series, such as barbitol, phenobarbital, amytal or pentobarbital sodium. The more rapid recovery from amytal or pentobarbital sodium offers no particular advantage in coronary disease, because a more or less persistent mild depression is desirable. By reducing nervous excitability the barbiturates are effective in reducing the number and severity of the attacks of

effort angina. By means of the barbiturates, one may control the fear and anxiety which intensify the distress of acute coronary thrombosis, as well as the restlessness which involves a dangerous expenditure of physical energy in this condition. In experimental studies<sup>13</sup> it has been found that these drugs reduce the susceptibility of the heart to ectopic rhythms and in that way may contribute to the prevention of ventricular tachycardia, which is one of the complications of coronary thrombosis.

It is advisable to use only moderate doses of these drugs. As a rule it is unwise to exceed from one-fourth to one-half grain of phenobarbital three times a day or from three-fourths to  $1\frac{1}{2}$  grains (0.05 to 0.1 Gm.) of pentobarbital sodium or analogous doses of some of the other members of the group. Large doses not infrequently cause a form of stupor associated with motor unrest and defeat the purpose for which they are used. The condition is analogous to the involuntary excitement stage of ether or chloroform anesthesia. If such a state has been produced, neither large doses nor substitution of another barbiturate solves the difficulty. The drugs must be discontinued for a day or two until sufficient elimination of the drug has taken place to reestablish the patient's normal control.

#### DIGITALIS

The use of digitalis in coronary artery disease constitutes the most widely debated of all questions concerning the treatment of this disease. Should it be given as a routine in these cases? Does it ever do any good? Is it always dangerous, or are there particular cases in which it is especially valuable or especially dangerous? Such are some of the questions on which clinical opinions are sharply divided.

In order to clarify the issues, it may be well to consider first what the conditions are in which digitalis is useful. There are two general indications: (1) cardiac failure and (2) certain disorders of rhythm with or without cardiac failure, namely auricular fibrillation, auricular flutter and possibly paroxysmal tachycardia.

Clinically, primary failure of the heart muscle manifests itself in two general forms. One is referred to as right ventricular or congestive heart failure. Its chief manifestations are dyspnea, orthopnea, distended veins of the neck, enlarged liver, pulmonary congestion, edema and ascites. The other is left ventricular failure in which the outstanding clinical phenomenon is one of recurring paroxysms of dyspnea or pulmonary edema. Very frequently the clinical picture represents a combination of the two.

A patient manifesting these disorders should receive digitalis regardless of what accompanying conditions are present. There are no contraindications that would preclude the use of digitalis in cases in which the foregoing indications for its use exist. Specifically, if a patient has auricular fibrillation with a rapid heart rate, or cardiac failure in the sense in which I have just described it, with coronary thrombosis as the cause or as an accompanying condition, the patient should be digitalized in the hope of favorably influencing the course of the failing power of the heart muscle. This applies to coronary thrombosis in any stage, either early or late.

There are, of course, many persons in the terminal stages of cardiac disease presenting these clinical pictures who appear to obtain little benefit from digitalis. Nevertheless, if a patient succumbs to right or left ventricular failure without having been digitalized, it is indeed difficult to controvert the charge that the patient has been deprived of a possible means of survival. No other agent is known that exerts such potent and protracted effects in increasing the power of heart muscle to carry a load. There seems to be no clinical or experimental evidence to support a contrary view, although other preferences and fears are frequently expressed.

This should not be taken to signify that most patients with coronary thrombosis should be digitalized, quite the contrary. The functional disorders of the heart for which digitalis is useful are very uncommon in the course of coronary thrombosis, and in the early days of an episode they are extremely rare. The disintegration of the cardiocirculatory function in coronary thrombosis appears to be a form of "shock" with peripheral failure, and digitalis is no more useful in this condition than it is in the peripheral circulatory failure of pneumonia, sepsis or traumatic shock. Dyspnea, orthopnea, enlargement of the liver, distention of the veins of the neck and edema are relatively rare symptoms in the early period of a coronary thrombosis. There is therefore no indication for the use of digitalis in the circulatory difficulties of most cases of acute coronary thrombosis, because in most of them the clinical signs of right or left ventricular failure do not occur. It should be noted at this point that the distinction of right or left ventricular failure from peripheral circulatory failure often presents great difficulties in coronary thrombosis. Many cases show temporary equivocal signs such as inconstant rales at the base of the lungs. In fact a sharp line cannot always be drawn between the two conditions. However, judgment as to which condition is present is the deciding factor, and it is our practice, in such cases, to withhold digitalis until unmistakable clinical indications of right or left ventricular failure appear.

An objection has been raised to the use of digitalis in those cases in which the drug can prove effective, namely those with auricular fibrillation and those with cardiac failure. The argument is frequently based on the possibility that digitalis may do harm rather than on the conviction that, for some strange reason, it will fail to exert its customary therapeutic effect on the heart muscle. Clearcut clinical proof that such harm is produced does not exist. The fear that digitalis may do some harm receives its support mainly from certain experimental results. Four dangers are generally considered. One is that the drug, by increasing the force of the heart's contraction, will promote a tendency to rupture the tenuous tissue of the infarct. The second is that digitalis increases the work of the heart. The third is that digitalis might predispose the heart to ventricular tachycardia, since digitalis and coronary thrombosis may each by itself precipitate this abnormal rhythm. The fourth is that digitalis constricts the coronary vessels and may further diminish the coronary blood flow.

Concerning the danger of rupture, it may be said that digitalis exerts no actions on the human heart which can cause the ventricle to rupture. It does not raise the intraventricular pressure. How can it promote rupture of the ventricle without increasing the

pressure by which it is ruptured? On the other hand, it should be borne in mind that failure of the heart leads to an increase in the diastolic pressure in the ventricle, giving rise to a force which may stretch the infarcted area and in that way promote rupture of the ventricle. The danger, therefore, lies not in giving digitalis but in withholding it from a patient who has heart failure in the course of coronary thrombosis.

With regard to increased work of the heart, it should be noted that in the absence of failure digitalis tends to decrease cardiac output and diminish the work of the heart. The reverse takes place with digitalis during heart failure, namely increased output and increased work.<sup>14</sup> What is often lost sight of, however, is that the increased work after digitalis is the result of an improved capacity for work rather than an increased demand for work as occurs in exercise. The heart becomes more efficient as the result of the digitalis.<sup>15</sup> Such a phenomenon cannot be viewed as unfavorable.

Concerning the coronary vasoconstriction, the experimental literature is inconclusive, some reporting constriction, others dilatation and still others no effect. An investigation of that subject was made in our clinic recently in 120 selected cases of effort angina.<sup>16</sup> Diminution of coronary flow was to be indicated by increase in the frequency or severity of the cardiac pain. In not a single one of these patients was the course of the pain influenced by even toxic doses of digitalis. We are forced to the conclusion that digitalis does not exert any direct constrictor action on the coronary circulation in patients with coronary artery disease.

As to the danger of precipitating toxic rhythms, the experimental facts are these. It requires as much as from 50 to 75 per cent of the fatal dose of digitalis in normal animals to precipitate ventricular tachycardia.<sup>17</sup> Doses necessary in therapeutic digitalizations are a long way from those which cause this toxic rhythm. Within anywhere from twenty-four hours to three weeks after coronary thrombosis it is found that animals require only three fourths of the usual dose to cause the ventricular tachycardia.<sup>18</sup> The only problem which this suggests is the desirability of giving smaller doses to treat cardiac failure in patients with coronary thrombosis, namely, about three-fourths as much as that subject might receive if he did not have a myocardial infarct. It is a matter of no great difficulty and involves no special hazards if one proceeds to digitalize when necessary by a method involving relatively small doses.

A satisfactory dosage in the average case of auricular fibrillation or heart failure in coronary thrombosis is about 6 grains or 0.4 Gm (4 cat units) of digitalis leaf daily for three days, followed by about 3 to 4½ grains or from 0.2 to 0.3 Gm (2 to 3 cat units) a day as long as necessary. The patient should be watched carefully for the appearance or increase in the

number of ventricular premature beats, which should serve as a guide to reduction of the dose. Such a plan carefully pursued involves no special risks to patients with coronary thrombosis.

#### DIURETICS

The indications for the diuretics overlap in part those for digitalis. They are useful for the control of congestive heart failure and attacks of paroxysmal dyspnea. An intravenous injection of 1 cc of salyrgan or meicupurin two or three times a week with or without a daily dose of 5 or 6 Gm of ammonium nitrate as the need may be often proves very helpful. The patient in whom this treatment is necessary should also receive digitalis.

#### QUINIDINE

Quinidine and the related alkaloids of cinchona have the same uses in cases of coronary disease as in all other types of cardiac diseases. They control troublesome premature contractions and abolish auricular flutter, auricular fibrillation and ventricular tachycardia. Ventricular tachycardia is the disorder most feared after coronary thrombosis, especially the more severe grades, in which the heart rate may rise to 250 a minute. The possibility that quinidine might be useful in small doses as a prophylactic in all cases of coronary thrombosis has received some attention.<sup>19</sup> Concerning this, it should be noted that it usually requires large doses to abolish the more severe forms of ventricular tachycardia, from 30 to 100 grams (2 to 6.5 Gm) in a period of several hours. There is no reason to believe that the small prophylactic doses of 9 grams (0.6 Gm) a day, as are recommended, are likely to prevent an attack of ventricular tachycardia in cases in which the larger doses would fail to abolish one within a few hours. Evidence concerning this matter is extremely difficult to obtain, but it is my belief that the prophylactic use of quinidine in this routine manner is without sufficient merit. To patients presenting premature ventricular contractions after a coronary thrombosis, an oral dose of 5 grains (0.3 Gm) of quinidine sulfate may be given three times daily, and the dose may be increased if necessary by 5 grains daily until the abnormal beats disappear or until minor toxic symptoms appear.

The intravenous injection of quinidine is dangerous and should not be used except in extreme emergencies, and then only by those familiar with its use.

It is well to bear in mind that auricular fibrillation or flutter caused by coronary thrombosis usually subsides spontaneously within hours or days, and unless the rate is unduly rapid and appears seriously to impair the circulation the condition may safely be allowed to run its spontaneous course. Quinidine should be used only if it appears necessary to expedite the restoration of the normal rhythm. If signs of congestive failure are present, digitalis is preferable to slow the ventricular rate in auricular fibrillation and to restore the normal rhythm in auricular flutter.

#### PAPAVERINE, IODIDES AND TISSUE EXTRACTS

Papaverine in one-half or 1 grain (0.03 or 0.06 Gm) doses exerts a mild general depressant action, and in animal experiments the drug relaxes smooth muscle. It appears to have little value, however, in the control of cardiac pain. While iodides are extensively

employed in the treatment of coronary sclerosis, not a vestige of evidence exists that they influence the symptoms or the course of the coronary disease in the absence of syphilis. Tissue extracts yield a host of vasodilator substances. They are widely exploited as "heart hormones" for the treatment of angina pectoris. If any one of the more optimistic reports represented the true value of these extracts, coronary disease would now have ceased to present a serious therapeutic problem. The reports are conspicuous by their lack of suitable control. It is idle to attribute the relief of pain to a substance given in a series of injections when the ritual of the treatment itself, as well as numerous other factors that have not been excluded, could have been responsible for the change. The critical reader cannot be impressed with the case that has been made out for the use of tissue extracts in coronary disease.

#### EMERGENCY MEASURES

There are several emergency situations arising in the course of coronary thrombosis in which drug therapy is extremely difficult to evaluate, namely shock, acute pulmonary edema, Adams-Stokes attacks and acute collapse at the onset of an attack in which the pulse disappears and consciousness is lost. Epinephrine is occasionally helpful in acute pulmonary edema, if the systemic pressure is low, and in Adams-Stokes attacks. There is danger in these cases of precipitating ventricular tachycardia. Solution of posterior pituitary should not be used for its vasopressor effect because of the constrictor action on the coronary vessels. Caffeine, metrazol, coramine and intravenous dextrose solutions are widely used in the peripheral failure of coronary thrombosis, but there are no satisfactory clinical studies that throw any light on their usefulness.

The detailed treatment of coronary disease is not within the scope of this discussion, but because only drugs have been considered there is danger that too much emphasis has been placed on them. It is therefore well to state that under proper supervision a large proportion of cases of effort angina as well as many with coronary thrombosis will run their course from beginning to end with little or no medicine, and this often with considerable advantage. The prevailing tendency appears to be to overtreat patients with coronary disease than otherwise, to give them too many drugs and too much of each. It ought also to be stated that, while in many instances great suffering is spared and a life is saved through the judicious use of these agents, the major part in the control of this disease lies not in drugs but in expert guidance in making the mental and physical adjustments which will enable these patients to carry on within their capacity without symptoms.

**Book on Gynecology by Trotula**—In the fifteenth century the first printing presses were set up in Europe for the general multiplication of books by an easier method than by the pen or brush, and no less than twenty editions of the "Regimen Sanitatis Salernitatum" were printed before the year 1500. Some of these bore the title "Flos Medicinæ Salerni." To the original compilation of this work, as we have seen, Trotula contributed largely. The first printing of her gynecology, the "De Passionibus Mulierum," under her own name, came from the press of John Schottus, in 1544.—Hurd-Mead, Kate Campbell. A History of Women in Medicine, Haddam, Conn., the Haddam Press, 1938.

A NEW INTERPRETATION OF HYPER-  
GLYCEMIA IN OBESE MIDDLE-  
AGED PERSONS

L H NEWBURGH, MD

AND

JEROME W CONN, MD

ANN ARBOR, MICH

The term diabetes mellitus has in the past implied a single cause. Ever since the days of von Mering and Minkowski this disease has been attributed to a pancreatic abnormality. However, within the last few years the work of a number of investigators has made it clear that this conception is far too restricted. Houssay,<sup>1</sup> for example, has shown that the rapidly fatal diabetes produced by pancreatectomy in animals may be strikingly ameliorated by subsequent hypophysectomy. In the same sense Mann<sup>2</sup> has produced fatal hypoglycemia in depancreatized dogs by hepatectomy. A number of workers have produced hyperglycemia and glycosuria by injection of pituitary extracts, and Young<sup>3</sup> reported that he obtained permanent "diabetes" in dogs solely as the result of prolonged injection of anterior pituitary extracts.

It is therefore clear that clinical investigators must now attempt to discover the specific cause of the hyperglycemia in all patients who present the classic signs and symptoms of the abnormality to which the clinical term diabetes mellitus is attached. In this paper we are endeavoring to show that we have isolated etiologically one group of persons characterized by obesity and spontaneous glycosuria.

Joslin<sup>4</sup> has emphasized the frequency of obesity in the patients who come to him for the treatment of diabetes mellitus. He reported on a group of 3,094 patients, 20 or more years of age, whose weight at the onset of the disease was known. Of the males 63 per cent and of the females 67 per cent were obese. Our investigation concerns only those patients who were obese and middle aged when they came to us for the treatment of spontaneous glycosuria.

Table 1 shows how many patients were obese when they were first accepted at the University Hospital during the year 1936 for the control of diabetes mellitus. It will be seen that close to two thirds of the patients who were from 30 to 65 years of age were overweight when treatment for diabetes was first begun. Since this middle-aged group accounted for 72 per cent of the patients, 44 per cent of all the patients treated for diabetes were obese and middle aged when they were first accepted for treatment.

These patients had been obese for many years. Glycosuria was often discovered in a routine examination of the urine. Generalized pruritus, pruritus vulvae, mild polyuria and polydipsia or visual disturbances often caused the patient to seek the physician. Glycosuria

may have been discovered several years earlier and been ignored without the development of any marked symptoms. On the other hand, some of the patients had been receiving treatment for diabetes for many years. The physical examination revealed no constant abnormality other than obesity. Hypertension was present in 40 per cent of the cases. Moderate hepatic enlargement was noted in 12 per cent. Cataracts were not uncommon.

## METHOD OF INVESTIGATION

We chose for study only those patients who were obese, middle aged and spontaneously glycosuric on an unrestricted diet. Each subject satisfying these conditions was fed a standard normal diet (300 Gm of carbohydrate, 80 Gm of protein and approximately the maintenance number of calories) for at least three days prior to a standard dextrose tolerance test. The amount of dextrose ingested (1.75 Gm per kilogram) was calculated on the basis of ideal weight.<sup>5</sup> If under these conditions the response was such that it would be generally accepted as indicative of diabetes mellitus, the patient was included in the group.

A number of the patients who conformed to the standard diagnostic criteria for diabetes mellitus described were studied with regard to their ability to oxidize dextrose. The data were obtained by means of

TABLE 1—New Cases in Which a Diagnosis of Diabetes Mellitus Was Made During 1936 at University Hospital

a respiration chamber employing the principle of continuous indirect calorimetry by the open circuit method.<sup>6</sup> The patients ate a standard preparatory diet for at least three days before the respiratory data were obtained. These data were compared with those obtained from normal control subjects under identical conditions.

Having secured these preliminary data while the subjects were both obese and glycosuric, we then placed them on reduction diets. No other treatment was instituted. The carbohydrate of the diet was reduced only to the degree made necessary by the restriction of calories. Dextrose tolerance tests were repeated during the period of weight reduction. These tests were done after the standard dietary preparation used for the original ones. Some of the patients were unwilling to adhere to the diet long enough for us to obtain any information. Only those who continued to reduce their weight by adherence to the diet were studied further. We are at present reporting the results obtained with thirty-five such patients.

The blood sugar was determined by the Benedict method<sup>7</sup> and the urinary nitrogen by the Kjeldahl

From the Department of Internal Medicine, University of Michigan Medical School.

The expense of this study was defrayed in part by a grant from the Horace H. Rackham and Mary A. Rackham Foundation.

glycosuric patient to be a deficiency in the mechanism by which glycogen is deposited rapidly in the liver. It seems evident therefore that the glycogenic mechanism is disturbed by the adiposity.

As far as is known there are two ways in which hepatic deposition of dextrose as glycogen may be impaired. First, a disturbance in the functional capacity of the liver cells themselves to lay down glycogen has been produced by the use of hepatotoxic chemicals and demonstrated in association with diseases of the liver.<sup>15</sup> Second, lack of insulin leads to an inability to deposit normal quantities of glycogen in the liver as well as to decreased oxidation of dextrose. If one wished to develop the latter hypothesis further with regard to the cases under consideration, he would be forced to conclude that a mild insulin insufficiency may reduce hepatic glycogen retention without at the same time affecting the oxidation of dextrose. If this is true, then this is the first demonstration in human beings that lack of insulin may adversely affect glycogen storage and yet not reduce the ability of the organism to oxidize dextrose. There are no facts available, however, that lead to the belief that insulin production is reduced by obesity. Nor is there evidence that removal of obesity increases insulin secretion.

On the other hand, we<sup>15</sup> have shown that hepatic glycogenesis, impaired in the presence of normal oxidation of dextrose in patients suffering from low grade infections of the biliary tract, becomes normal when the cause of the hepatitis is removed. It therefore seems more likely that in the type of patients discussed in this paper the abnormal accumulation of fat in the liver interferes with its capacity to lay down glycogen at the normally rapid rate.

#### CONCLUSIONS

1 A statistical analysis of spontaneous glycosuria associated with delayed disposal of ingested dextrose indicates that approximately half of the patients are obese. These obese glycosuric patients are, with few exceptions, more than 30 years of age.

2 After the weight of these patients has been reduced to normal by simple underfeeding, they remain aglycosuric, do not become hyperglycemic when they are placed on maintenance diets containing 300 Gm of carbohydrate and exhibit normal dextrose tolerance curves.

3 There is an occasional exception to this rule, but more than 90 per cent of the patients respond in this manner.

4 Recurrence of the obesity is capable of reproducing the hyperglycemia and the delayed utilization of dextrose. Subsequent reduction of weight again corrects the disturbance in the metabolism of carbohydrate.

5 It has been demonstrated that the majority of persons who have been obese for many years show delayed utilization of carbohydrate. Since the majority respond in this way to adiposity and again dispose of carbohydrate normally when the excessive weight has been removed, this phenomenon must be regarded as being the type response of the previously normal mechanism carbohydrate metabolism to the overload of obesity.

6 It is suggested that the occurrence of the hyperglycemia and glycosuria in such persons depends on the

excessive accumulation of fat in the liver, with a resulting impairment in its capacity to lay down glycogen at the normally rapid rate.

7 The studies described establish a clinical entity in which obesity is the principal abnormality and hyperglycemia is a secondary phenomenon.

#### ABSTRACT OF DISCUSSION

DR BERTNARD SMITH, Los Angeles. Clinically, it is well to keep in mind that this obese group, even with the mild degree of diabetes, continue to show poor diabetic control with large doses of insulin so long as they remain obese. They can tolerate large doses of insulin without the usual sharp hypoglycemic reactions. A report of studies on a small group of these patients has recently been given by Duncan and his associates of Philadelphia. In this group of patients the severity of the diabetes cannot be measured by the units of insulin taken so long as excess body weight is present. The respiratory studies in this report are of particular interest and are in agreement with studies on the respiratory quotient in similar groups of patients in indicating that the obese middle-aged person with diabetes of mild degree can oxidize dextrose. The diabetic condition must be due to a difficulty in glycogen formation and storage. Whether this difficulty concerns only hepatic glycogen remains a problem. Not all obese persons of middle age are diabetic, and not all show dextrose tolerance curves indicative of even potential diabetes. The group of patients included in this report have been shown to be definitely diabetic while obese. They become aglycosuric, with a normal amount of sugar in the blood so long as they follow such dietary restrictions as maintain an ideal weight. When these restrictions are not followed, loss of diabetic control results. The use of the word "cure" may subject the authors to some criticism, since the diabetic condition would appear to be present even with the perfect control of weight. This group of obese diabetic persons of middle age does not include all patients with diabetes of the insulin-resistant type. During my early studies with protamine insulin, sixty-two juvenile diabetic persons were under observation, and twenty-five of these were definitely of the insulin-resistant group. Also, among middle-aged patients with insulin-resistant diabetes will be found some who do not come under full diabetic control with reduction of body weight. These patients, in whom the diabetes appears to be more severe, will still require the help of insulin after weight has been reduced. However, the insulin requirement after reduction of weight may be small, and the diabetes may show more even control than before. It is possible that the persons with more severe insulin-resistant diabetes may have some defect in oxidation of dextrose as well as the decreased ability to store glycogen.

DR J. W. SHERRILL, La Jolla, Calif. The members are indebted to Drs. Newburgh and Conn for calling attention to this classification which they have made in diabetics. They have described relief from diabetic symptoms in this type which might be classified as the potential or prediabetic type. This work helps to explain the mildness of this condition which was recognized formerly as the prediabetic type. This differs remarkably from the true diabetic as well as the juvenile type, in that the patients preserve the ability to oxidize dextrose. If the definition of diabetes, that it is a condition in which there is failure to utilize dextrose, is to be adhered to carefully, then it cannot be said that this type would be classified as diabetes. Studies with the respiration chamber show a normal ability to oxidize dextrose. The group differs from normal persons only in that they are unable to clear their blood in normal time. Drs. Newburgh and Conn have demonstrated in graphic form the well known factor in diabetic treatment, namely, that reduction of body weight or body mass increases ability to burn dextrose and carbohydrate tolerance. Certainly they have shown that the reduction of obesity is the mechanism whereby they obtain normal tolerance curves and the ability to metabolize a normal diet. Nevertheless, physicians must still be cautious, as these persons probably have an impairment of insulogenic function. It is well known that the standard carbohydrate tolerance tests of a group of obese persons in the

15 Conn, J. W., Newburgh, L. H., Johnston, Margaret W. and Sheldon, J. M. A Study of Deranged Carbohydrate Metabolism in Chronic Infectious Hepatitis. Arch. Int. Med. 62: 765 (Nov.) 1938.

normal population reveal impaired curves in direct relation to the duration of obesity. Therefore, before the 'void cure' can be used in this instance these patients would have to be studied several years hence say ten years, because possibly it is not the obesity itself which has produced this decrease in carbohydrate tolerance but a deficiency in pancreatic function. One can hardly get away from this factor because by permitting these persons to become obese again impairment in their carbohydrate tolerance can still be demonstrated. It would be well to keep in mind that the duration in years may bring about diabetes of a more specific character in this group. This contribution will be helpful particularly from the insurance angle for the group of persons who have been denied insurance in the past. It may permit them to obtain insurance to which they are entitled.

DR FRANK N. ALIAN, Boston. Every one will agree with the facts presented by Drs. Newburgh and Conn and will feel pleased to see these results. Yet I share the opinion that their conclusions cannot be accepted without challenge. Can one say that diabetes has been cured simply because tests for blood sugar made after treatment give negative results? One would not say that heart disease is cured when signs of decompensation disappear. I think the authors should be asked to report the fate of these same persons twenty years from now or even five years from now. It is not uncommon to find that diabetes which has become latent will cause trouble later on as a result not only of neglect but of the strain of infection or other misfortune. Can one say that these patients do not have real diabetes simply because of inability to demonstrate any change in oxidation in the body? The difference may be only a matter of degree. Diabetes of only the slightest degree now may become so severe as to endanger life later on, particularly if the condition is aggravated by infection. Let this report be accepted as confirming the favorable prognosis which may be expected in diabetes associated with obesity. That gives hope and encouragement. But the diagnosis of diabetes should not be abandoned; this will surely lead to neglect and eventually to disastrous results.

DR J. W. COON, Ann Arbor, Mich. We were unable in the time allotted to discuss some of the points brought up. The question that Dr. Smith raised is this: Do all obese middle-aged persons have some degree of this disturbance in the metabolism of carbohydrate? If this disturbance is due to obesity, it should be found in all middle-aged obese persons. A large number of dextrose tolerance tests done by Kisch, Paulin and Sauls and by John indicate that from 60 to 70 per cent of all of these apparently normal people without glycosuria have lessened dextrose tolerance. The work of Ogilvie seems to answer the question of why the other 30 to 40 per cent of obese people gave a normal response. He found that impaired tolerance was related to duration rather than to degree of obesity. Thus, after eighteen years of obesity every patient in his series showed diminished dextrose tolerance. I should like to answer Dr. Sherrill's question regarding the prediabetic state. One considers the so-called prediabetic state that in which the patient shows a diabetic type or a tendency toward a diabetic type of dextrose tolerance curve but does not have sufficient rise in the sugar content of the blood to cause spontaneous glycosuria. When a patient has spontaneous glycosuria and a diabetic type of curve, he is called diabetic. The obese patients with glycosuria that we have described do not fall into the group considered by some to be prediabetic. Our group comes to the clinic with heavy glycosuria, a blood sugar value during fasting as high as 350 mg. per hundred cubic centimeters and a dextrose tolerance curve rising as high as 550, and after reduction of weight the dextrose tolerance test is normal. After the weight becomes normal these patients are not given diets. They are told to eat whatever they care to eat, candy, ice cream, potatoes and bread. They are simply instructed that they must not gain weight. Under this kind of a regimen, these patients have remained aglycosuric and have shown normal dextrose tolerance for two years thus far. Regardless of all theoretical considerations, the fact remains that obese middle-aged persons with glycosuria hitherto diagnosed and treated as true diabetes mellitus can regain and retain the normal metabolism of carbohydrate by simple reduction of weight to normal.

SPREADING PERITONITIS COMPLICATING ACUTE PERFORATIVE APPENDICITIS

ROUTINE OPERATIONS VERSUS SCIENTIFIC MANAGEMENT

JOHN O. BOWER, M.D.  
PHILADELPHIA

Routine defined means any regular course of action or procedure adhered to through force of habit.

Fifty-three years ago Fitz described acute appendicitis, and since then opinions and procedures of surgeons adhered to through force of habit have been responsible for the major part of the management of patients suffering with this disease and its complications. No more striking illustration of this fact can be found than what is called the mortality of acute appendicitis. During these five decades, thousands of articles have been written about it, eminent men who are relied on for accurate statements regarding the mortality of the disease have used the term, but there is practically no mortality from acute appendicitis. One in 183 dies. Patients die of peritonitis, not appendicitis.

Likewise because of force of habit surgeons have not discussed with physicians the problem of spreading peritonitis complicating acute appendicitis. Physicians

TABLE 1—Mortality of Appendicitis and Appendical Peritonitis

	No. of Cases	Deaths
Acute appendicitis	12,259	67—1 in 183 died
Acute appendicitis with local peritonitis	3,835	88—1 in 44 died
Acute appendicitis with spreading peritonitis	2,573	694—1 in 4 died
Total	18,667	849—1 in 22 died

know that the mortality of acute appendicitis as reported throughout the United States is anything from zero to 5 per cent. Do they know that the gross mortality of spreading peritonitis is from 27 to 50 per cent? According to Hoffman, the average mortality rate of appendicitis per hundred thousand in Philadelphia was 134 from 1928 to 1933. During the same period in the United States it was 171. The average mortality of spreading peritonitis in Philadelphia was 26.97 per cent. According to this ratio it must have been at least 33 per cent throughout the United States.

Have surgeons told physicians that the surest method of reducing the mortality of spreading peritonitis is to send to hospitals patients whose appendices have not ruptured?

In Philadelphia, the third largest city in the United States, with a population of over two million, a prophylactic campaign has resulted in a reduction in the number of patients with perforated appendices admitted to twenty-eight hospitals, with a corresponding reduction in the mortality for appendicitis of from 5.97 to 3.54 per cent. Three hundred and sixty-five surgeons have managed a gradually diminished number of patients with spreading peritonitis, but in the last four years the mortality has not been materially reduced.

Are surgeons and not physicians responsible for this situation? Is it significant that during the past fifty years the number of articles on acute appendicitis published in reputable medical and surgical journals in

Read before the Section on Surgery, General and Abdominal at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

the United States and England exceeded the number on spreading peritonitis by 500 per cent? Would not the American Medical Association be justified in suggesting to the editors that they refuse articles on acute appendicitis for publication? Furthermore, would it not save time and a great deal of money if all labora-

Fig 1—Location of forty-six perforated appendixes that were the cause of spreading peritonitis

tories would stop sectioning appendixes? Millions of sectionings are done each year, and what good comes of them? What do patients die of? Not what is seen within the confines of a serous membrane by the microscopist and not what is seen at postmortem examination by the pathologist, but what is not seen at operation by the surgeon

Is it true that patients die of what the surgeon does not see at operation? Figure 1 shows the location of forty-six perforated appendixes that were the cause

TABLE 2—Comparative Mortality of Appendicitis and Spreading Peritonitis

	Appendicitis Mortality per 100,000	Spreading Peritonitis Mortality, Percentage
Philadelphia	13.4	26.97
United States	17.1	?

of spreading peritonitis, in each case the process was permitted to localize, the abscess was drained and the patient was discharged from the hospital and readmitted later when the appendix was removed. With a spreading process, how much can one actually see with any type of incision?

When an appendix perforates and the reactive capacity of the patient is within normal limits, resultant gross tissue changes can, for practical purposes, be divided according to three zones, a central, a middle and a peripheral (fig 2). In the central zone, part or all of the perforated appendix is found, partially or completely covered by omentum or by fibrinous or fibrinopurulent exudate, in the middle zone the cecum and adjacent loops of ileum and omentum approximated and partially covered with plastic exudate, are found, and in the peripheral zone the changes are indetermi-

nate. The central zone and usually part of the middle zone are visible. The peripheral zone should not be seen. What happens to the patient is determined there in the front line trenches, where micro-organisms invasion either advances or is checked by processes which must not be disturbed.

The greater the number of explorations of the peripheral zone, the higher the mortality. Table 4 illustrates this point. In twelve hospitals during one year, 171 patients with spreading peritonitis were operated on an average of fifty-seven hours after the onset of symptoms, in 164 cases or 95.7 per cent.

TABLE 3—Mortality for Appendicitis and Spreading Peritonitis

Year	Appendicitis		Spreading Peritonitis	
	Perforated Percentage	Mortality Percentage	Admitted Percentage	Mortality Percentage
1925-1929	42.06	5.97	13.4	1.93
1930	11.4	4.01	15.2	26.37
1931	3.0	4.9	1.62	24.4
1932	29.62	1.44	12.80	22.10
1932	26.25	3.34	12.63	24.61

the appendix was removed. Of the patients operated on, 37.4 per cent died. This table indicates that the mortality of spreading peritonitis increases with the radius of activity of the surgeon.

Figure 3 shows what happens when the peripheral zone of the spreading processes is explored. Approximately 85 per cent of the appendixes were removed in this series. The horizontal line represents the day of disease. The vertical line represents the percentage mortality, which is 20 for the first twenty-four hours, it increases consistently to 36 on the fifth day, drops to

Fig 2—The three zones of gross changes in the tissue

35 on the sixth, and then to 26 on the seventh day. Of the 2,573 patients operated on, 694, or 26.97 per cent, died.

In direct contrast to the results following radical surgical intervention are those obtained when immunologic processes are permitted to develop undisturbed.

Of 18,687 patients who had acute appendicitis and were admitted to the twenty-eight hospitals, 3,855, or

20.63 per cent had a localized abscess and only eighty-eight, or 2.28 per cent, died. A majority of the eighty-eight died because the localized process was markedly disturbed at operation, they died because the appendix was searched for or removed, they died because a localized process was converted into a spreading one, they died of induced spreading peritonitis. This statement requires an explanation.

Fig. 3—Mortality of spreading peritonitis in 2573 cases (from 1928 to 1933) twenty four hour groups. C cases, D deaths.

On the clinical records of over 90 per cent of those who died, the cause of death is written by the intern was the same as the diagnosis on admission, local peritonitis. Patients rarely die of acute appendicitis and they seldom die of local peritonitis, they die of spreading peritonitis. The records showed that after operation hyperpyrexia, tachycardia and inflammatory ileus developed, the patients died of induced spreading peritonitis.

The following years show a reduction in the mortality of local peritonitis from 3.79 per cent to 0.93 per cent, or over 400 per cent because of the fact that surgeons had fewer patients to manage and the patients admitted with a local abscess which was later converted into a spreading process by operation were placed in the group where they belonged, that of spreading peritonitis.

Another factor in the low mortality of the localized abscess is the result of immune processes, the local manifestation of which is the formation of an abscess.

TABLE 4—Routine Operations and the Mortality of Spreading Peritonitis

Hospitals	Spreading Peritonitis			Appendix Removed Percentage	Average Hour Between Onset and Operation

wall. The experienced surgeon limits his operative procedures to its confines, he will not remove an appendix that extends beyond or forms a part of this wall.

I wish to call attention to another wall, a wall that is thin, a wall that is difficult to see and hence is frequently disrupted, a wall that encloses a process in which the micro-organisms are virulent. I refer to a wall formed by omentum and the peritoneal surface of contiguous intestine cemented together with plastic exudate, this wall forms the outer boundary of the localizing process in the center of which is an appendix. This process is responsible for 10 per cent of the 27 per cent mortality of spreading peritonitis in Philadelphia.

Both the abscess and the localizing process are nature's attempts to cure an infection, the stage of immunologic development is the main difference. In the localized abscess not only is there a well developed wall but the tissues forming the wall and those contiguous to it have developed an immunity and in a large percentage of cases antitoxin is circulating in the blood stream.

In the localizing process the wall of protection is in the formative stage, as are local and general immunity.

TABLE 5—Mortality, Local Peritonitis

Year	No. of Patients Admitted with Acute Appendicitis	Local Peritonitis		
		Number Admitted	Admitted Percentage	Mortality Percentage
1928-1929	121	102	28.38	3.79
1930	362	625	20.19	1.76
1931	342	618	19.66	1.82
1932	346	572	16.13	0.89
1933	373	438	14.22	0.93
	18687	3855	20.63	2.28

If this localizing process is not disturbed it will develop into a localized abscess and the patient will be protected by fully developed immune processes, but if it is disturbed, if the appendix is removed, in most instances spreading peritonitis will be induced and the patient has one chance in four instead of one chance in forty-four of dying, a difference of 1,100 per cent.

The appendical abscess in its formative stage—the localizing process cannot be successfully managed as if

Fig. 4—Localized abscess

it were a fully developed abscess—the surgeon, when he suspects an early perforation or when he inadvertently encounters one, must think before he proceeds. He must substitute for routine procedures a management based on a workable knowledge of immune processes, he must know about antigens and antibodies and the part they play in the mortality of appendical

peritonitis Before he separates adherent loops of intestine before he pushes omentum aside, before he inserts his finger into a developing abscess he should know that he is injecting into the blood and lymph stream a dose of antigen that kills one in every four to ten patients A dose of strychnine for adults is 0.015 Gm the lethal dose is 0.2 Gm The lethal dose

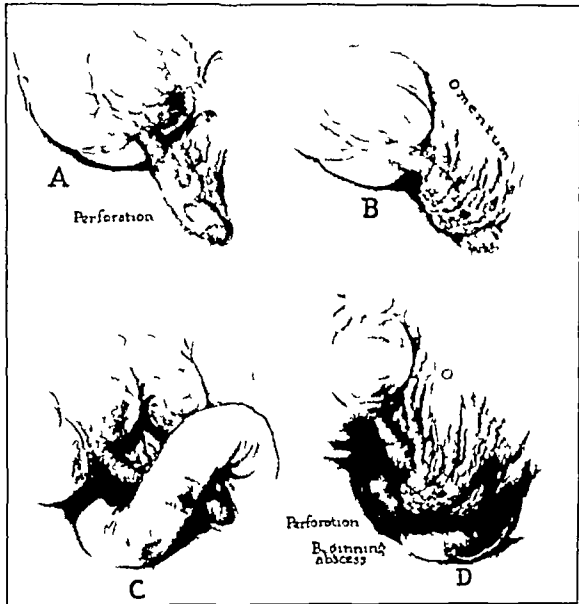

Fig. 5—Wall formed by omentum and the peritoneal surface of contiguous intestine cemented together with plastic exudate

of the antigen which the surgeon is about to give the patient is approximately the same as the lethal dose of strychnine, 0.013 Gm will kill ten pigeons each weighing 350 Gm

Figure 6 shows what happens to patients with appendical spreading peritonitis who received the lethal dose of *Clostridium welchii* toxin and other bacterial antigens Hyperpyrexia, tachycardia and delirium

TABLE 6—Standardization of *Perfringens* Antitoxin Prescribed by the National Institute of Health

0.013 Gm of <i>Clostridium welchii</i> toxin plus 1 cc of perfringens (welchii) antitoxin

0.013 Gm of <i>Clostridium welchii</i> toxin is equivalent to ten minimal lethal doses

develop and the patient dies How many patients die like this? A large percentage of the 18,000 who die each year in the United States at the average age of 27 The patient whose chart is shown in figure 6 received three doses of antigen, the first was absorbed from the mucous membrane of the serosa-intact appendix, the second when the appendix perforated and the third when I searched for and removed a leaking appendix, the last dose being given when the patient was in the so-called negative phase

Figure 7 shows what happens when a patient receives two doses of antigen but is not operated on in the negative phase This patient received one dose before rupture and one at the time of rupture but not the third, because I placed the drain down to but not into

the localizing process At the second operation for removal, the appendix could not be found, it was completely absorbed

How do I know that what I have said about antigens is true? Because my associates and I have titrated the blood serum of patients who have recovered from spreading peritonitis and the peritoneal exudate removed from patients having unruptured acutely inflamed appendices

In the titration of both serum and exudate the technique prescribed by the National Institute of Health was carried out at the Mulford Biological Laboratories of

TABLE 7—Summary of Experimental Work on the Titration of Blood Serum for *Clostridium Welchii* Antitoxin

	Number of Patients	Number Showing Antitoxin	Incidence of Antitoxin Percentage
In normal health	10	0	0

Sharp and Dohme A 350 Gm pigeon was given a toxin-antitoxin mixture containing 10 minimum lethal doses of *Clostridium welchii* toxin and 1 cc of antitoxin This should result in the death of the pigeon within twenty-four hours

The control pigeons those that received the toxin antitoxin mixture plus 1 cc of normal serum, died We then added to this toxin-antitoxin mixture 1 cc

Fig. 6—Clinical chart of a patient who received the lethal dose of *Clostridium welchii* toxin and other bacterial antigens

of serum from patients who had recovered from acute appendicitis, 22.22 per cent showed the antitoxin of *Clostridium welchii* in their blood serum, with another group 1 cc of serum from patients who had recovered from pelvic peritonitis was added to the toxin-antitoxin mixture, and 46.66 per cent showed antitoxin in their

serum. Finally we removed the serum from patients who had recovered from appendical spreading peritonitis and antitoxin of *Clostridium welchii* was present in 70.59 per cent. One patient in the last group had had spreading peritonitis nineteen years previously.

We then titrated the peritoneal exudate removed from patients suffering with acute appendicitis and

cularly. The mortality was 15.39 per cent. In a second group, forty-six patients, operation was deferred for 196 hours. They were given the Ochsner routine before and after operation and were given perfringens antitoxin in addition to dextrose in saline solution intravenously. The mortality for the group of forty-six patients was 6.52 per cent and for the ninety-eight patients 11.22 per cent.

Figure 8 shows the opening of the localized abscess from the roof, which is usually done with local anes-

TABLE 9—*Lavative-Induced Spreading Peritonitis Complicating Acute Perforative Appendicitis*

	Number of Patients	Hours Between Onset of Symptoms and Operation	Perfringens Average Dose, Cc	Mortality Percentage

thesia. After separating the fascia and muscles, the index finger palpates the mass beneath. If it is not resilient, one assumes that there is an abscess beneath and it is opened. If, however, the mass appears to be intestine, palpation is continued, the incision closed and a second made over the suspected point of contact of the abscess with the peritoneum.

Fig. 7—Clinical chart of a patient who received two doses of antigen but was not operated on in the negative phase.

found that this fluid contained antitoxin to the toxin of *Clostridium welchii* in 33.33 per cent of instances.

The exudate for the first titration test was removed from the peritoneal cavity ten and one-half hours after the onset of the patient's second attack of appendical colic. It contained sufficient antitoxin to save the lives of three pigeons. The blood serum was then titrated,

TABLE 8—*Summary of Experimental Work on the Titration of Peritoneal Exudate for Clostridium Welchii Antitoxin*

	Number of Patients	Number Showing Antitoxin	Incidence of Antitoxin Percentage
With acute appendicitis	15	5	33.33

and it also contained sufficient antitoxin of *Clostridium welchii* toxin to save the lives of three pigeons.

These and other investigations, reported elsewhere, have resulted in a management of appendical spreading peritonitis which has for its basis the development and the preservation of local and general immunity. Briefly, it is the Ochsner routine, used until localization occurs, the giving of perfringens antitoxin and lyophile peritonitis convalescent serum, and the opening of the abscess from the roof.

Table 9 shows the results obtained in the management of ninety-eight patients with appendical spreading peritonitis. Fifty-two of these patients were operated on immediately after admission, an average of 54.6 hours after onset. In addition to dextrose given intravenously in physiologic solution of sodium chloride, they were given 44.73 cc of perfringens antitoxin intramus-

Fig. 8—Opening of the localized abscess from the roof.

The number of patients treated with lyophile peritonitis convalescent serum is not sufficiently large to report at this time.

SUMMARY

Routine operation as it pertains to the management of acute appendicitis and its complications should be limited to the nonperforative appendix. When the serous coat is intact, it makes no difference whether

the inflammation in the tissue beneath is catarrhal, suppurative or gangrenous, only one patient in 183 dies

Scientific management based on the development and the preservation of local and general immunity should be carried out when the serous coat of the appendix is ruptured

2008 Walnut Street

#### ABSTRACT OF DISCUSSION

DR HAROLD P. TOTTEY, Los Angeles My conception of the progress of peritonitis following perforation differs somewhat from that expressed by Dr Bower. It has been my experience that, while deferred operative treatment with a strict Ochsner regimen is a valuable procedure, it is not without hazard. It is well to remember that removal of the source of peritoneal contamination is one of the fundamental requirements in the treatment of perforative peritonitis from any source. Cases showing evidence of localization with abscess formation when first observed are best treated by operation deferred until about the seventh or eighth day, when surgical intervention may be safely undertaken. This period is early enough to avoid late complications. In the case of spreading peritonitis, however, a different situation obtains. The condition is progressive and it is very difficult to tell with any degree of certainty what course the disease will take or how effective expectant treatment will be in causing a subsidence or localization of the inflammatory process. Furthermore, there are a number of cases in which perforation takes place at the appendiceal base so that there is a continuous gross peritoneal soiling, and death will ensue from local peritonitis unless the leak is stopped, irrespective of the condition of the general peritoneal cavity. In view of these considerations and in the absence of evidence of localization or subsidence, granting that the condition of the patient permits, I have felt that surgical intervention is indicated after a reasonably brief period of observation and preparation. By adequate preparation and reduction of the surgical procedure to its simplest form, the range of operability may be increased to a maximum. Spinal and local anesthetics are to be preferred. Too much stress cannot be placed on the value of the McBurney incision. Placed just medial to the anterior superior iliac spine, it permits one to perform the operation practically as an extraperitoneal procedure if there is a tendency toward the formation of protective adhesions and if the appendix is readily accessible. If the appendix is not accessible, simply incision and drainage are indicated. Drainage is accomplished by the use of soft rubber tissue Penrose drains inserted along the parietal peritoneum and not between intestinal coils. Placed in this manner they will not disturb protective adhesions nor will they act as a source of intestinal obstruction. In severe infections the wound is closed by suturing the peritoneum loosely about the drains. This procedure aids drainage and combats the growth of anaerobic organisms. Enterostomy as a primary procedure is a life-saving measure in the treatment of intestinal obstruction incident to peritonitis and is indicated in cases that are potentially obstructive. Its use has been largely superseded by the Levine tube with suction except in cases that are obviously dynamic in character.

DR DAVID A. WILLIS, Chicago When a diagnosis of appendicitis has been established, with the exception of appendiceal abscess or definitely localizing cases past seventy-two hours, I have seldom delayed operation for I have too frequently been deceived by the pathologic signs in their relation to the symptoms. This seems particularly true in children, in whom the localizing ability is distinctly diminished. It is not surprising to discover in the child after a week's illness a suppurative appendix practically unprotected by omentum or adjacent bowel. Under such circumstances a ruptured appendix continues to pour out virulent organisms with which the peritoneum cannot long cope. In my series of cases of ruptured appendicitis the mortality rate has been distinctly lower than the average despite the fact that over a period of fifteen years I practically always closed the abdomen without drainage. I do, however, through an approach very close to the anterior superior iliac spine always attempt to limit the operation to the central zone. In an analysis of the cases of ruptured appendicitis treated by a number

of surgeons, it was found that the relation of the age of the patient to the mortality rate and the nature of death presented features strikingly common to all. Though about 35 per cent of the cases of ruptured appendicitis were represented by children under 10 years of age, the great majority of deaths resulting from this condition occurred in this class of patient. In a series of cases of appendiceal abscess it was found that though children represented approximately one third of the total number of cases they actually accounted for nearly all the deaths and produced a mortality rate of 40 per cent for their own class. Another significant fact was that the manner of death in these so-called abscess cases in children was similar to that following nondelayed operation for ruptured appendicitis. The child immediately after develops a rapidly rising temperature and pulse and dies within twelve to twenty-four hours with what appears to be an acute vasomotor collapse due to acute toxemia. Experience indicates two things: first, that the appendiceal abscess in the child may be more apparent than real and as such makes questionable the advisability of delayed operation. Second, that the child with ruptured appendicitis succumbs quickly to the toxin in delayed and nondelayed operation and suggests the urgent necessity of a measure to combat the acute toxemia. If these observations are correct, then in view of Dr Bower's remarkable success in lowering the mortality rate a slight delay for immunizing purposes with a substantial amount of antitoxin and lyophilic serum in addition to the usual preoperative measures may be the course to follow.

DR W. D. HAGGARD, Nashville, Tenn. The prompt operation for acute appendicitis in the early hours is ideal. Operation for spreading peritonitis is often ill advised and yields frightfully high mortalities. Many surgeons are swayed by the general feeling among the profession that a patient with appendicitis must be operated on whenever he is seen, irrespective of the duration and no matter how severe the complications. When used as an ironclad indication for operation it is pernicious. We are using our poorest surgical judgment in the fear of an evil result without operation. Many of us have called attention to the fact that the dangerous delayed third, fourth and fifth day cases of peritonitis should be delayed for preparation and to let nature accomplish her wonderful biologic protection. Taking the appendix out in the presence of spreading or generalized peritonitis is like rescuing the overturned lamp that has set the house on fire. The chemical engine is better. This new antitoxin will be welcomed. This scientific addition is to amplify what nature is doing for the patient and will give us something to do while anxiously awaiting improvement before operation. I have advocated delayed operation in delayed cases of appendicitis for some years. One can open a ten to fourteen day appendiceal abscess practically extraperitoneally and almost all the patients will get well. If we intervene before nature has partially or completely walled off the process we are interfering at a notoriously inopportune time. No wonder our mortality is above 25 per cent. Having seen how the unmolested peritoneum encapsulates an acute appendiceal process and neutralizes infections by the antitoxin, local and general, that the patient himself manufactures, we shall be greatly heartened to refrain from injudicious operation and utilize this new antitoxin against micro-organisms that the patient cannot neutralize unaided. We should give this antitoxin in the advanced, neglected, delayed cases the third, fourth and fifth day, giving every other supporting and preparatory treatment. I believe the best thing Dr Bower has told us is not to give the third and fatal dose of the toxin with the operating finger, give it in a hypodermic

DR JOHN OSCAR BOWER, Philadelphia There is a difference between individual and hospital mortality. I am sure that most surgeons have a very low mortality individually but the mortality that I have reported is hospital mortality and there is a great difference. The mortality of 365 surgeons in Philadelphia operating on 18,000 patients with spreading peritonitis is 27 per cent. I know that every man here will say that his individual mortality of spreading peritonitis is much lower than that. One thing that has been brought out in the discussion is the seriousness of the management of this disease in children. The general conception is that one should treat children differently from adults. I have not found it so. Children develop antitoxin just as adults do and localize in the same way. I put in drains after

they have localized, give dextrose and saline solution intravenously and antitoxin or convalescent serum or both. I know definitely that 60 per cent of the patients who recover from spreading peritonitis have the antitoxin of *Clostridium welchii* in their blood serum. What other antibodies they have I do not know. So far as the mortality in the age group is concerned, the average age of those here today is between 40 and 50, no matter what type of appendicitis develops, the death rate is just about 10 per cent. The mortality between 60 and 70 is about 50 per cent. Close without drainage? No, I do not believe that is the right thing to do. There are many reasons why I believe this is not indicated. Mention was made of the removal of the drains. I believe that the drains should be permitted to remain in seven days at least. I have reviewed many cases in which the removal of the drains has converted a localizing process into a spreading one. I use the McBurney incision. I do not believe that the so called leaking appendix is hazardous; it is not common. It must be remembered finally that patients recover from spreading peritonitis just as they do from pneumonia or a cellulitis. They recover because they develop a local and general tissue immunity.

## THE ACTION OF MEASURED DOSES OF EIGHT HUNDRED KILOVOLT ROENTGEN RAYS

ON CARCINOMA OF THE UTERINE CERVIX

HENRY SCHMITZ M.D.  
HERBERT E. SCHMITZ M.D.  
AND  
JOHN F. SHEEHAN M.D.  
CHICAGO

The solution of the problem of adequate control of carcinoma of the uterine cervix by irradiation with roentgen rays in the region of 800,000 volts comprises the study of the clinical aspects of the disease and the etiology, the pathology and the symptomatology, including the extent of the disease and the action of the radiation on the tumor and the cancer cells. The investigations reported in this communication are confined to the last two factors. It may be assumed that the degree of macroscopic and microscopic changes is dependent on the dose of radiation. These changes take place during treatment and continue for some time afterward until arrest of the cancer has or has not been attained. The observations to be reported include, therefore:

1. A consideration of the factors used in the production of the radiation which determine the intensity or quality of radiation and the duration in time of the application. The dose of radiation is the product of intensity and time.

2. A study of the visible changes taking place in the tumor. The desired local reaction is complete absorption of the tumor, leading to complete anatomic recovery with normal epithelization of the portio.

3. A study of the microscopic changes occurring in the cancer cells. Lysis of all cancer cells and not incarceration of viable carcinoma cells within dense connective tissue should be the goal.

Therefore, the dose of radiation, the local visible and palpable changes in the tumor and the microscopic reactions in the cancer cells will be discussed. The investigations were arranged so that records were kept of the dose of radiation applied in the midpelvis, of the

local conditions found on examination and of the changes seen in the carcinoma cells at stated intervals. The duration of treatment was four weeks, and reexaminations were made at eight day intervals during and at fifteen or thirty day intervals after treatment. The cases were not selected but taken in rotation. Therefore, the report represents all clinical groups according to the classification established in our institute.

### THE DOSE OF RADIATION

The favorable results of irradiation depend on many factors, such as the histologic index of malignancy, the sensitivity or resistance to radiation and the dose of radiation applied at the periphery of and within the tumor.

The dose of radiation is the product of the quality or intensity of radiation and the duration of application.<sup>1</sup> The factors used in the production of the roentgen ray determine the quality. They were 800 kilovolt maximum obtained from a double pulsating Villard current, a load of 10 milliamperes on the x-ray tube, which is rendered gas free by oil vacuum pumps, a water cooled tungsten target, a filter equivalent to 10 mm of copper, a focal skin distance of 70 or 86 cm, field sizes varying from 10 to 20 square centimeters, and a half value layer of 8.2 mm of copper, corresponding to an average wavelength of 0.028 or a minimum wavelength of 0.0128 angstrom unit. The output of roentgens per minute measured with a thimble chamber was 36 roentgens without and 44 roentgens with backscatter. The dose attained at a depth of 10 cm measured in a bakelite phantom is 54.5 per cent of the surface intensity if the size of the entrance field is from 300 to 400 square centimeters. The number of fields whenever practicable was two pubic and sacral. Since more than 90 per cent of the patients had an anteroposterior diameter of 23 cm or less, it rarely became necessary to use more than two fields. The amount of radiation required to produce a tolerance skin dose with 800 kilovolt roentgen rays is 4,000 roentgens if applied in ten fractions at forty-eight hour intervals. If two fields are used, the midpelvic dose is the same as that attained on the skin, or about 4,000 roentgens, at the lateral bony pelvic walls as well as in the midpelvis. The rate of recovery of the tissues after each fractional dose has not been subtracted. It is not as yet known what the rates of recovery of the normal in contradistinction to the abnormal tissues are. The dose attained within the pelvis after seven days was 1,000 roentgens, after fourteen days 2,000, after twenty-one days 3,000 and after twenty-eight days 4,000, with backscatter.

### THE LOCAL CHANGES

The local reactions of a carcinomatous cervix have been studied by Farrar,<sup>2</sup> Neef<sup>3</sup> and Stewart<sup>4</sup> among others after intracervical insertions of radium and by Ewing<sup>5</sup> after 200 kilovolt roentgen therapy. The reactions after the application of 800 kilovolt roentgen rays are practically the same. Within seven to ten days after the beginning of treatment hyperemia and capillary injection of the surface around the growth are seen.

During the second week a whitish pseudomembrane covers the cervix, and after twenty-eight days necrosis appears leading to a blackish green discoloration of the bed of the growth. During the sixth to eighth week the necrotic tissue separates and is cast off, leaving a granulating surface. This is followed by epithelization

Fig 1 (case 14)—Transitional cell carcinoma after irradiation with 300 roentgens. Comparison with pretreatment biopsy specimen revealed only mild swelling of nuclei and cytoplasm. (Slightly reduced from a photomicrograph with a magnification of 500 diameters). All photomicrographs in this paper were made with the same magnification. Any change in the cellular or nuclear size is real and not the result of change in magnification.

when the prognosis is favorable and by persistence of granulation or friability of tissue when it is unfavorable. Biopsy alone can tell whether one is dealing with radiation necrosis, arrest of the growth of the tumor cells or recurrence or continuation of the primary carcinoma. Recurrence or persistence of the primary carcinoma means retreatment by irradiation. We prefer to use radium filtered with 2 mm of lead and 1 mm of aluminum or with 1 mm of platinum. The dose should be 1,500 mg element hours, repeated once or twice at intervals of eight days.

#### THE MICROSCOPIC CHANGES

Studies of microscopic changes in cancer cells due to radiation have been reported by Degrais and Bellot,<sup>6</sup> Schottlander,<sup>7</sup> Schmitz,<sup>8</sup> Alter,<sup>9</sup> Frankl and Amreich,<sup>10</sup> Neef<sup>3</sup> and Englmann<sup>11</sup> among others. The conclusions with regard to the significance of such changes, of course, vary. They should be based on the histologic index of malignancy, the grade of sensitivity or resistance to radiation and the dose of radiation. Inde-

quate doses may stun the cancer cells temporarily, adequate doses cause lysis of all tumor cells, overadequate doses may lead to temporary or permanent radiation necrosis.

The study of the microscopic changes due to 800 kilovolt 100tgen irradiation was made from biopsy material. Tissue was removed before the onset of treatment and thereafter every seven days, corresponding to tumor doses of about 1,000, 2,000, 3,000 and 4,000 roentgens. Thereafter, tissue was obtained at each follow-up examination, namely every fourteen days for the following three months. If epithelization or healing had ensued, the cancer was considered arrested. If granulation or friable tissue persisted, the biopsy would contribute to the diagnosis either of harmless granulations enclosing normal epithelial cells or of persistence or recurrence of the cancer. The biopsy specimens were obtained with a punch without the use of the cautery. They were spherical and approximately 4 mm in diameter. All specimens after the inception of treatment were fixed in Bouin's fluid and stained with hematoxylin and eosin.

Of the original twenty-five patients chosen for this study, eleven were discarded, some because they failed to cooperate, others because there was some question about the accuracy of the pathologic diagnosis made before admission to this clinic. The diagnoses for the remaining fourteen were as follows: transitional cell carcinoma for nine (three of these showed a few cornified cells and four others a few spindle cells), spindle cell carcinoma with cornification for three (two of these showed a mantle of transitional cells near the stroma, surrounding the spindle and cornified cells), spindle cell

Fig 2 (case 14)—Section removed after irradiation with about 4,000 roentgens. Many bizarre nuclear forms are present; pyknosis is marked. (Slightly reduced from a photomicrograph with a magnification of 500 diameters.)

carcinoma for one (a few transitional cells were intermixed with the spindle cells), and adenocarcinoma of colloid type for one.

The changes noted in the carcinomas included (1) swelling of the cytoplasm and nuclei of the tumor cells, the cytoplasm staining palely basophilic and the nuclei becoming more vesicular with accentuation of the

nucleoli, (2) loss of regularity in the pattern of the tumor, with increasingly great variation in size, shape, structure and staining qualities of the nuclei, (3) increasing cornification in the masses of tumor cells predisposed to cornification, (4) relative increase in abnormal mitoses and increase in the number of cell

Fig 3 (case 14)—Section removed one week after completion of treatment (from 4,000 to 4,500 roentgens). Few tumor cells are present. The stroma is increased and the nuclei are enormous. There is marked irregularity of the nuclear contours and the nuclei are markedly hyperchromatic and pyknotic. A nucleus in the lower left portion of field persists as a basophilic smudge. Fine vacuolation of the cytoplasm is present in one cell. (Slightly reduced from a photomicrograph with a magnification of 500 diameters.)

monsters, i.e., cells with giant hyperchromatic nuclei or multiple nuclei, (5) obliteration of the boundaries of cells, (6) bizarre nuclear forms, with irregularities of the nuclear membranes, (7) karyolysis, particularly marked in cells with palely basophilic, swollen cytoplasm, (8) pyknosis, most marked in cells with giant hyperchromatic nuclei and rather deeply eosinophilic cytoplasm, (9) neutrophilic infiltration in partially or completely cornified masses of cells, (10) foreign body giant cells in apposition to masses of keratin, (11) fine and coarse vacuolation of the tumor cells, and (12) decrease in the size of sheets of tumor, with relative increase in the amount of stroma.

The changes in the fibromuscular coat of the cervix included (1) surface ulceration with necrosis and neutrophilic infiltration, (2) a zone of edema beneath this layer, with swelling of capillary endothelium and granulations, (3) swelling of collagen and ultimate hyalinization, often most marked around capillaries and arterioles, particularly in the deeper tissues, (4) necrosis of the capillary endothelium and the walls of the arterioles with thromboses, noted only at the margin of the necrotic surface, (5) swelling of collagen and hyalinization in the subendothelial tissues of the walls of the small arteries, with narrowing or occlusion of the lumens and rarely with thrombosis, more marked in the deeper vessels, and (6) atrophy of smooth muscle.

In the noncancerous cervical epithelium edema, vesiculation and desquamation of the stratified squamous epithelium were noted. Relatively little variation in the columnar epithelium was encountered.

The changes just enumerated showed a certain sequence in response to increasing doses of radiation. To make these more intelligible, a distinction must be drawn between cells with little or no tendency toward cornification and those with such potentialities. In the first group (group 1 cells) are included the spindle cells, the bulk of transitional cells and some of the spinal cells, notably those peripherally located in the sheets of tumor i.e. near the stroma. The second group (group 2 cells) comprises partially cornified cells and the spinal cells near cornified cells. Some transitional cells probably should be included here, as our observations seem to indicate direct cornification of some transitional cells without previous conversion into spinal cells. In general it may be said that cells of the first group, under the influence of increasing doses of radiation, have a tendency to assume either of two forms: (1) that of markedly swollen cells with palely basophilic cytoplasm, at times finely vacuolated and with single large vesicular nuclei or multiple small nuclei showing a trend toward karyolysis, and (2) that of large, even enormous cells, with giant hyperchromatic nuclei and rather dense eosinophilic cytoplasm, showing little vacuolation, the nuclei tending definitely to become pyknotic. These will be referred to hereafter as the large palely basophilic type and the large eosinophilic type, respectively.

The cells of the second group (prone to cornification) assume two main forms: (1) that of small cells with single or multiple bright red intracytoplasmic masses, apparently composed of keratin, and with small, distorted, compressed and even pyknotic single nuclei, and (2) that of larger cornified plates. Hereafter these will be combined under the term "cornified cells."

Fig 4 (case 22)—Transitional cell carcinoma after irradiation with 1,000 roentgens. The general pattern of an untreated tumor has been retained. Comparison with the pretreatment biopsy specimen revealed only moderate uniform swelling of the cytoplasm and nuclei. (Slightly reduced from a photomicrograph with a magnification of 500 diameters.)

By the end of the first week of therapy (after about 1,000 roentgens) the most notable change was rather uniform moderate swelling of the cytoplasm and nuclei of the tumor cells of group 1. The swollen cells had a palely basophilic, finely reticulated cytoplasm, and their nuclei showed some vesiculation with accentuation of the nucleoli. The nuclear dimensions had increased.

from an average of 6.5 by 10 microns to 10 by 13 microns in one case, and from 7 by 13 to 13 by 19 microns in two others. Scattered larger nuclei, about 13 by 26 microns, were noted, these were more numerous than at pretreatment biopsy. Group 2 cells showed increasing cornification. Neutrophilic infiltration was noted in certain groups of cornified cells.

By the end of the second week (after about 2,000 roentgens, a more marked effect was evident. Much of the regularity in the pattern of the untreated tumor had been lost. In tumors with group 1 cells (not readily cornified) more marked variations in size, shape and staining qualities of the nuclei were noted. Numerous cells of the large eosinophilic type with enlarged nucleoli were noted. Some of these were pyknotic. However, the large palely basophilic type predominated. Fine vacuolation of the cytoplasm and fading of the nuclei were noted in many of these. In tumors com-

be observed. Vacuolation of the cytoplasm was rather marked. In tumors with group 2 cells cornification was much more extensive, some nests of tumor cells being completely cornified. The few transitional cells and spinal cells which persisted as a poorly defined mantle around some cornified cells showed changes described at this stage for group 1 cells.

By the end of the fourth week after the onset of treatment (after about 4,000 roentgens) the qualitative changes in group 1 (noncornifying cells) were about the same as at the end of the third week, but quantitatively more cells of the large eosinophilic type were noted, and in these there was greater irregularity in the shape and outlines of the nuclei. Pyknosis in these was much more pronounced. Some of these giant nuclei, robbed of cytoplasm, persisted as large basophilic smudges. However, the large palely basophilic cells were also in evidence. Karyolysis in these was much more marked, some of the cells having lost their nuclei entirely. Particularly large nuclear forms were found, a few reaching a size of 30 by 75 microns. The largest seen measured 45 by 102 microns. In tumors with group 2 (cornifying) cells almost all the cells were cornified, and foreign body giant cells were noted in apposition. The compactness and large size of the sheets of tumor cells in the untreated tumor disappeared, only small masses of tumor cells remained.

The summary just given represents general trends. Our biopsy material included only the superficial portions of the tumors close to the surface necrosis produced by radiation. Furthermore, the changes in every tumor were not as uniform as the summary might indicate. In one case a definite deviation was noted in a biopsy specimen taken at the end of the third week of therapy. Near the necrotic surface the large eosinophilic type predominated, about 1 mm deeper the large palely basophilic type was in the ascendency. Two millimeters deeper, tumor resembling that in the pretreatment biopsy specimen and showing but little effect of radiation was noted.

Many of the cases included in this investigation were followed by biopsy for several months after the completion of treatment. In four cases no tumor was noted even thirteen weeks after cessation of therapy. In two of these the tumor had disappeared by the end of the second week of roentgen therapy. In other cases the tumor persisted and the previously listed effects of radiation on tumor cells were noted as long as five weeks after the completion of treatment but no definite recurrence was in evidence. In seven cases, however, there was definite recurrence in some cases as early as two weeks after completion of therapy. The reappearing tumor showed the features observed at pretreatment biopsy. No effects of radiation were present. In these cases radium therapy was subsequently given.

The one adenocarcinoma of the cervix in this series was of the mucous gland type. Before therapy the glands were lined for the most part with tall columnar cells. Flattened cells were also noted. The changes in these cells included those listed previously for group 1 cells but were milder. Swelling of cells and nuclei, the disappearance of cellular boundaries, the appearance of eosinophilic cells with large pyknotic nuclei and paler cells showing some karyolysis and finally the complete loss of much of the epithelial lining of the gland spaces were noted. The few remaining cells were notably damaged. The mucus in the gland spaces seemed to become denser as irradiation continued.

Fig. 5 (case 22)—Section removed after irradiation with about 3,000 roentgens. The swelling is more marked than in a section removed after 2,000 roentgens. There are more bizarre nuclear forms. An enormous multinucleated cell can be seen in the lower right portion of the field. Note the vacuolation of the cytoplasm, neutrophilic infiltration, karyolysis and pyknosis. (Slightly reduced from a photomicrograph with a magnification of 500 diameters.)

posed of group 2 cells (readily cornified) the cornification of the central cells in the tumor masses had progressed at the expense of the mantle layer of spinal and transitional cells around them. In this mantle layer the changes noted at this stage in group 1 cells had occurred.

By the end of the third week (after about 3,000 roentgens) the sheets of tumor cells were smaller than before and the cytoplasm and nuclear boundaries more irregular, poorly defined or even indistinguishable. In tumors with group 1 cells, swelling seemed to have reached or to have passed its peak. More bizarre nuclear forms were noted. Some of these tumors were composed now only of cells of the large eosinophilic type, and pyknosis and nuclear lobulation were much more prevalent. In other tumors of this type, however, the large palely basophilic type was in the ascendency, with karyolysis and particularly multinucleation prominent features. Clusters of small nuclei, numbering as many as fifteen or twenty to a single cell, could

No definite sequence was noted in the changes in the fibromuscular tissues of the cervix or in the noncancerous cervical epithelium. Swelling of collagen, most marked around capillaries or in walls of arterioles, was noted by the end of the first week of therapy. The changes in the subendothelial tissues in the walls of small arteries were most pronounced by the end of the third week, although noted as early as the end of the first week. These changes were not particularly severe. Edema and vesiculation of the epithelium were also noted by the end of the first week but were not constant features.<sup>12</sup>

No prognostic significance could be attached to the presence of numerous eosinophils in the inflammatory exudate in the tumors included in this series. In two cases in which their presence was a rather prominent feature, the carcinoma had disappeared by the end of the second week of therapy. However, in some cases in which the carcinoma persisted or recurred, eosinophils were also in evidence, particularly in one case in which recurrence and even invasion of the broad ligaments were noted shortly after completion of therapy.

In another series of cases clinical observations unsupported by microscopic examination of biopsy specimens after completion of therapy established a rate of four year clinical cure of 50 per cent with the same therapy used in this investigation. In the present series, checked by repeated biopsy, the absolute disappearance of carcinoma was noted in four cases (about 25 per cent). In seven cases (50 per cent) definite recurrence was noted. Degenerated tumor cells were still present in the remaining three cases. The cases, however, have not been followed for a sufficient length of time to determine whether the degenerative changes are an omen of ultimate complete disappearance. The clinical results of a 50 per cent arrest of cervical cancer after four years might support such a hypothesis.<sup>13</sup> These studies will be continued in an endeavor to determine this point as well as the value of repeated biopsies.

#### SUMMARY

The gross and microscopic changes occurring in a series of fourteen carcinomas of the uterine cervix when subjected to 800 kilovolt roentgen therapy were observed.

A pronounced action of these rays on carcinoma cells with a relatively mild effect on the normal tissues was noted.

The significance of persisting, though markedly degenerated, tumor cells weeks after completion of treatment cannot be appraised at this time. Further studies may clarify the matter. It might be assumed that these cells remain inert from the fact that 50 per cent of growths treated more than four years ago have become clinically arrested.

The value of repeated biopsies after the completion of therapy, as used in this investigation, cannot be sufficiently well appraised at this time.

Biopsies at stated intervals coinciding with the application of known tumor doses may aid in the recognition of growths which have been irradiated inadequately. Such growths should then be retreated with the object of increasing the good clinical end results.

#### ABSTRACT OF DISCUSSION

DR DANIEL G. MORTON, San Francisco. I have examined microscopically sections from the cervixes of numerous patients first irradiated and later operated on. In the majority the Memorial Hospital technique was used, occasionally this was supplemented by roentgen therapy. As the operations were performed at varying periods after the irradiation, it was possible to observe the effect of time. The changes produced by 800 kilovolt irradiations are qualitatively similar to those produced by radium but appear to be slower in developing, as pronounced effects are demonstrable after radium within fourteen to twenty one days. The persistence of cancer cells in many of the cervixes after full irradiation occurs after radium also in about half the cases. When these cells are degenerate forms their significance is difficult to assay. Such cells may be dying dead or merely injured. The persistence of cancer in the cervix after full irradiation emphasizes that irradiation cannot yet be trusted to destroy all local cancer. This applies to both radium and x-rays. These pathologic changes also explain the fact of frequent local recurrences, even in early cases, examples of which I have noted repeatedly. The immediate gross reaction to irradiation is often deceptive. Good surface healing may occur but is not necessarily indicative of cure as cancer often persists in the tissue depths in spite of good surface response. This occurred in many of our specimens and taught us that a prognosis could not be made on this basis. I can see no advantage in excluding radium from the treatment of cervical cancer. I have learned that the field of effectiveness of radium is limited yet within its field the destructive effect on cancer is definite and valuable. It seems clear that high voltage radiations should also be used, as they appear to be capable of reaching and killing cancer cells in regions of the pelvis inaccessible to radium. At the University of California Hospital the percentage of five year survivors after irradiation has been almost doubled since the addition of 200 kilovolt therapy. Following Taussig's work we have been removing the regional glands in certain borderline cases in which irradiation had been done previously. Some of our patients have received roentgen therapy preoperatively and some have not. Eventually it should be possible to demonstrate a difference in the incidence of involved glands in the two groups if the x-rays are in fact capable of destroying cancer in these locations, as most of us believe that they do.

DR ROBERT R. NEWELL, San Francisco. Knowledge of the usefulness of supervoltage falls in three categories, namely physical tissue dose at surface and in the depth, reaction of cells and tissues to these doses and response of tumors. Theory and measurement have made it clear that the physical depth dose is better when high voltages are used. Expressed in percentage the superiority of supervoltage is not very great, but it is real and for thick parts like a pelvis, especially a fat woman's pelvis, it is undoubtedly of clinical importance. Evaluation of superiority in clinical results by going to supervoltages is not easy to establish as firmly as the physical measurements. The authors have already contributed to our knowledge in this category. The present paper concerns the second category, tissue reactions attained by supervoltage. It is a striking experience to see radiation-reactions in the cervix produced by external irradiation similar to what we have previously known only by local irradiation or radium. In our own clinic, using 350 kilovolt x-rays filtered to give a half value layer of 5 mm of copper, my associates and I have succeeded in attaining roentgen reactions qualitatively but not quantitatively similar to what we look on as essential for the cure of epidermoid cancer in the mouth or on the face. In fact we know that it is not today possible, even with a million volts, to get by external irradiation tissue doses in the uterine cervix even a third as large as what we consider standard practice with radium. It would still seem necessary to add local irradiation (radium or Chaoul) to the cervix itself. Now the advantage of external irradiation is that it has filled the whole pelvis with therapeutic reaction, of which the authors are reporting samples from the cervix. This fills in the defect in radium treatment to the cervix—I mean, the discouraging insufficiency of tissue dose in the parametria. In those widespread cases of cervical cancer which we classify as groups 3 and 4, one might well rest one's therapy just with external irradiation. But if one has any hope that the cancer

<sup>13</sup> Schmitz, Henry, Schmitz, Herbert E. and Sheehan, J. F. Clinical Observations on the Treatment of Primary Carcinomata of the Cervix with 800 kv Roentgen Rays. *Am J Obst & Gynec* 35: 405 (March) 1938.

is confined within a couple of centimeters of the cervix, then I would think one ought to use radium too. And if four weeks of x-ray cross-fire has at all shrunk the cancer, so much the better chance that it is now all within reach of the radium.

DR L. H. GARLAND, San Francisco. It has been my privilege for some years to observe the end results on patients treated with supervoltage roentgen irradiation at the San Francisco Hospital. We do not have a supervoltage unit at that institution but receive patients from the other institutions in the city, two of which have supervoltage units. It is generally agreed among careful observers that equal doses of 200 kilovolt radiation and 1,000 kilovolt radiation produce identical changes. Supervoltage therapy has no magic except that the large output of supervoltage machines permits the therapist to apply it more efficiently to some deep-seated lesions. It is my impression that carcinomas of the uterine cervix, whether treated with orthovoltage or supervoltage, always need additional radium irradiation for cure. In his discussion Dr. Morton made one statement which must be challenged, and that is that viable cancer cells persist in the cervix in 50 per cent of patients treated with radium, immediately after the end of treatment. Dr. Morton is referring to cases inadequately treated with radium, that is to say, treated with about 3,500 milligram hours of radium. It has been demonstrated by Heyman, Regaud and others that the great majority of cases of carcinoma of the cervix need between 7,000 and 10,000 milligram hours of radium for cure. They need such a dosage whether the filtration is 2 mm. of brass or 1 mm. of platinum. Following such dosage suitably spaced only a small number of cases will fail to show significant local destruction of cancer immediately at the end of treatment. Whether one treats cancer of the cervix by irradiation or by surgery, it is not the size of the x-ray machine or the sharpness of the surgeon's knife that enables one to cure the cancer; it is the skill and judgment of the physician in radical therapy. It is the voltage of the physician's brain and not of the machine which helps to cure the condition.

DR. MORTON. In remarking that cancer persisted in 50 per cent of cervixes previously completely irradiated, I was referring to a number of cases in which radium irradiation was carried out and later followed by the Wertheim operation. The radium technic which we have been and still are following at present is that in use at the Memorial Hospital in New York and involves the use of a basic dose of 4,500 millicurie hours. This may be supplemented according to circumstances. In the majority of our cases, the radium dosage was in the neighborhood of 4,500 millicurie hours, in a few it was less, and in a few, more. The matter of correct or sufficient dosage remains as yet an unsettled question. The percentage of actual gamma rays which arrive in the tissues depends to some extent on the amount of screening. The screening of those employing the higher dosages is much greater than that which we have used, and therefore comparisons expressed in so many millicurie hours are not possible.

DR. HENRY SCHMITZ, Chicago. The questions arising in radiation therapy are from a physical and biologic standpoint so intricate that it is an impossibility to answer them by general statements. In 1915 at a meeting of the American Medical Association in San Francisco I presented one of the first papers written in this country on the influence of radium on carcinoma cells in the uterine cervix, and we have been interested in this work ever since. The distribution of radiation intensity from radium is so diffused and decreases so rapidly from the source of the irradiation that one is at a disadvantage from the very beginning when one has to treat a large area. The second important point is the radiation dose. One cannot compare a group of cases which have been adequately treated by such amounts of radiation that would kill or degenerate the cancer with those groups of cases which have been treated with comparatively very small inadequate doses. And no matter how one may try either by radium or by 200 kilovolts, extending the tolerance dose by using interstitial radiation, one will not be able to produce or send into the true pelvis such enormous doses of homogeneous radiation intensities as one can with higher voltage. I would not wish to say that the curative results from supervoltage are eventually going to be better or that it is worth while to go to the enormous expense and worry if the same results

could be attained with the combination treatment of radium and 200 kilovolt x-rays. One must remember, reviewing the large amount of material that has been accumulated in the surgical and radiologic treatment of carcinoma of the cervix, that the five year absolute good end results from surgical treatment are probably from 20 to 25 per cent, and the absolute five year good end results from the treatment of carcinoma of the cervix with radium are probably 25 per cent or somewhat higher. If we can increase these end results to 35 per cent or 40 per cent (and some Europeans are now reporting 35 and 40 per cent five year cures) and if we can do this by the introduction of supervoltage which gives a better distribution of an adequate homogeneous dose, then we shall have to find ways to install supervoltage transformers.

## ULCERATIVE GASTRITIS AND RESIDUAL LESIONS

H. E. ROBERTSON, M.D.

ROCHESTER, MINN.

One who is interested in the subject and who peruses the voluminous writings on chronic gastritis may be struck by the thought that for a matter in which the clinical manifestations are fairly definite and the pathologic characters are readily observable and easily catalogued there is a curious excess of speculation, arbitrary conclusions and disturbing contradictions.

Even Henning,<sup>1</sup> whose treatise covers most of the important observations which have been made concerning chronic gastritis, leaves one with a sense of futility, if any effort is made to harmonize signs and symptoms with the pathologic pictures which he so graphically presents.

Perhaps it is fortunate for me that I am not directly concerned with the clinical phases of this question. But I have studied these sufficiently to realize their exceedingly great complexities and to appreciate the reason for so much comparatively fruitless writing about them. Furthermore I am convinced that any attempt to correlate clinical phenomena with a given set of pathologic conditions is foredoomed to failure, for at one time a particular group of lesions may account for one fairly definite clinical picture and at another time or in another person an entirely different collection of symptoms or none at all may result as far as can be observed, from identical pathologic alterations.

The stomach represents a very complex physiologic mechanism affected almost as frequently and as severely by extrinsic as by intrinsic factors. When an extrinsic influence, such as a lesion in the brain or a severe anemia, upsets this mechanism the resulting disturbances may in turn bring about local changes which further complicate the clinical picture.

But these perplexities are for my colleagues in clinical medicine to solve. My present concern is in my own field of pathologic anatomy where some observations and deductions from these may serve to clarify somewhat the fundamental factors which produce such diverse lesions in the stomach.

It is well, here, to consider some of the peculiar anatomic features of the gastric mucosa. If one injects the arterial trunk with any substance which permits the capillaries to be visualized, they will appear in the mucous membrane as an extremely thick network so

From the Section on Pathologic Anatomy, the Mayo Clinic. Read before the Section on Pathology and Physiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

1. Henning, Norbert. *Die Entzündung des Magens*. Leipzig: J. A. Barth, 1934.

numerous that by dilating them with India ink one will see that the surface resembles a solid mass of this black substance. Whenever, for any reason an abnormal congestion of these capillaries occurs, one receives the same impression of a tremendously rich capillary blood supply to the entire mucosa. In ordinary microscopic preparations even of freshly preserved normal stomachs, these capillaries are but inadequately seen, but their importance in the interpretation of many lesions in the stomach cannot be overestimated.

This importance is emphasized by the fact that in the otherwise perfectly normal stomach the most frequent pathologic change is hemorrhage in the superficial layers of the mucosa (fig 1). Apparently whenever congestion of the capillary network occurs, even with the normal physiologic stimuli of digestion a slight overdistention in any local area may bring about a rupture of one or more capillary loops. Many of the causes of these hemorrhages are well known. Excesses of food or drink, abnormal congestions, poisons of many kinds, local infections, mental disturbances, fevers and anemias are but a few of the conditions in which gastric hemorrhages have been observed. As soon as the hemorrhage occurs, necrosis of the involved part is an inevitable result. This necrosis is promptly digested and leaves an ulcer, which ordinarily is promptly repaired with complete restoration of the integrity of the mucosa. In most instances probably the entire process is without a single discoverable clinical sign or symptom, unless perchance the modern science of gastroscopy may reveal these comparatively silent "hemorrhage-necrosis-ulcer" syndromes.

These lesions have been directly studied, among others, by William Beaumont<sup>2</sup> in the stomach of his noted patient Alexis St. Martin. Some of his observa-

Fig 1—Hemorrhage in the superficial layers of the gastric mucosa, stained with hematoxylin and eosin slightly reduced from a photomicrograph with a magnification of 25 diameters.

tions and conclusions deserve direct quotation. On page 99 he said:

In undue excitement, by stimulating liquors, overloading the stomach with food—fear, anger or whatever depresses or disturbs the nervous system—the villous coat becomes somewhat red and dry. There are sometimes found on the internal coat of the stomach eruptions or deep red pimples at first sharp pointed and red, but frequently becoming filled with white purulent matter.

Again, on page 252 there was the following report:

August 3, 7 o'clock a.m. Inner membrane of stomach unusually morbid—the erythematous appearance more extensive and spots more livid than usual from the surface of which, exuded small drops of grumous blood. Notwithstanding this diseased appearance of the stomach no very essential

Fig 2—Residual lymphocytes in the mucosa of the stomach, stained with hematoxylin and eosin ( $\times 77$ ).

aberration of its functions was manifested. Aug 6, 8 o'clock a.m. Stomach empty, coats clean and healthy as usual.

Further, on page 254, he said:

Diseased appearances, similar to those mentioned above, have frequently presented themselves, in the course of my experiments and examinations. They have generally, but not always succeeded to some appreciable cause. Improper indulgence in eating and drinking, eating voraciously or to excess, swallowing food coarsely masticated, invariably produce similar effects. These morbid conditions are however seldom indicated by any ordinary symptoms, or particular sensations described or complained of. They could not in fact, in most cases have been anticipated from any external symptoms and their existence was only ascertained by actual, ocular demonstration.

It is interesting [he added] to observe to what extent the stomach may become diseased, without manifesting any external symptoms of such disease, or any evident signs of functional aberration. Extensive active or chronic disease may exist in the membranous tissues of the stomach more frequently than has been generally believed.<sup>3</sup>

Surgeon Beaumont was unquestionably observing small focal hemorrhages which resulted in necrosis, often followed by leukocytes and other elements of an exudate with occasionally a pseudomembrane formation. These lesions then became small localized ulcers, which rapidly healed and apparently left the stomach restored to its normal state. The word "apparently" is used advisedly because, while many small hemor-

<sup>3</sup> These observations and conclusions have been abundantly substantiated by recent gastroscopic studies of living stomachs.

changes and their resulting ulcers may be followed by complete restitution, often there remain more or less definite gross and microscopic evidences of the fact that, after one or more local areas in the stomach have previously suffered from ulcers, imperfect instead of perfect healing has resulted. By imperfect healing I

Fig. 3—Depression in gastric mucosa with lymphocytes stained with hematoxylin and eosin (X85)

mean that, while the outer layer of mucosal cells may be perfectly restored and, to the unaided eye, the entire mucosa may appear absolutely normal, study of stained sections by the microscope reveals certain lesions which I assume to be the residual alterations accompanying the incomplete restoration of the deeper layers.

The most constant of these signs is one or more collections of lymphocytes in the mucosa (fig. 2). These are usually located close to the muscularis mucosae, are almost always sharply localized and range in size from only a few cells to large follicle-like aggregations, some with secondary centers. They may occupy the entire thickness of the mucosa and may even appear in the submucosa. In the region of the larger collections there may be depressions in the mucosa and a comparative diminution or even entire absence of the specialized peptic and acid cells (fig. 3).

In the healing of deeper ulcers, various deformities of the muscularis mucosae occur. Local fibrous tissue thickening is often present and frequently fibrous strands extend various distances toward the surface, occasionally partially enclosing small groups of gland cells and lymphocytes (fig. 4). With more severe processes, the submucosa is invaded and transformed into a compact fibrosis, sometimes even invading the muscle layers.

Even more striking are the changes in the glands. Besides depressions in the mucosa and atrophy of the specialized cells, the mucous glands become more prominent, often with wide and corkscrew-like lumens and broadened bases which occasionally spread out along

the thickened fibrous muscularis mucosae (fig. 5) or become cystic dilatations (fig. 6). A few glands may be caught in the meshes of the fibrous tissue and in rarer instances will be found sequestered in the submucosa (fig. 7). Paneth cells are often present. Associated with these changes the mucous glandular cells may exhibit evidences of increased rapidity of growth, such as larger and more numerous cells, hyperchromatic nuclei and even mitotic figures.

The residual lesions after the healing of more severe ulcers are, then, collections of lymphocytes, irregular fibrosis of the muscularis mucosae, atrophy of the mucosal differentiated elements and disorganization, often with hyperplasia of the fundamental mucous glands. At first such changes are strictly localized, but later with more widespread involvement practically the entire gastric surface may be affected.

As the residuals of ulcers increase in extent and magnitude, subsequent ulcers probably occur more frequently and heal more sluggishly, thus advancing more deeply into the wall and in turn giving rise to more severe secondary lesions. In this connection it is fitting to inquire as to what influences may be active in promoting or hindering the prompt healing of gastric ulcers. There is probably good reason to assume that the acid peptic juice secreted by the specialized gastric cells alters materially the forces which in general govern the healing of wounds. In our laboratory we have long been interested in the digestions of the stomach and esophagus which are prone to occur following death from lesions of the brain. This erosion often acts so promptly and extensively that some special combination of influences must be presumed to be present. In a special study of these stomachs my associates and I have been struck by the comparative absence of mucus on the digested surfaces. In certain instances a definite line of thick mucus has marked the limit of the eroded area. This fact has suggested to us that perhaps these

Fig. 4—Stomach hyperplasia of glands and disorganization of muscularis mucosae stained with hematoxylin and eosin, slightly reduced from a photomicrograph with a magnification of 85 diameters

postmortem phenomena are accelerated by the lack of a protective coating of mucus. Without the layer of mucus the gastric juices etch the stomach wall. Further it is highly probable that mucus performs a similar function during life and may be the sole factor which prevents the stomach from digesting itself. When hemorrhage in the mucosa produces necrosis, the pro-

duction of mucin in that area ceases and the necrotic zone is promptly digested until the living glands are exposed and fresh mucous reserves can once more inhibit the action of the digestive ferments. The lack of sufficient mucin as to either quality or quantity may thus account for the failure of proper or prompt heal-

Fig 5—Dilatation and distortion of mucous glands in the stomach stained with hematoxylin and eosin slightly reduced from a photomicrograph with a magnification of 77 diameters

ing of certain ulcers. The part played by lesions of the brain in postmortem digestion is, of course, not understood. We know all too little about the influences which promote or retard the secretion of mucus, one of the most important substances in the body. The possibility that some nervous mechanism, definitely affected by cerebral conditions, may play a role in the elaboration of this substance has to be seriously considered. Perhaps this mechanism may account for the well known fact that nervous states have a definite influence on the healing of gastric and duodenal ulcers, as is so often strongly suggested by the effects of proper rest in such cases.

As Beaumont observed smaller, more superficial ulcers disappear and leave a stomach apparently normal. However, if the ulcer is deeper and more severe, after healing a stellate scar may be clearly visible as a residual gross lesion. If the atrophic processes are marked, local depressions may result or, when they become more generalized, a thin flattened mucosa is a characteristic appearance. When hyperplastic changes become prominent the mucosa may be raised in ridges or local bosses and, if these are generalized, there results a cobblestone appearance which was designated by Stoerk<sup>4</sup> as "état mamellonné."

The frequency with which such appearances as those just described are found in stomachs in which carcinomas develop strongly suggests the possibility that under certain circumstances these hyperplastic changes in the mucous glandular cells may proceed to the stage of autonomous new growth. Thus it would appear that the old controversy concerning the question as to how frequently carcinomas develop in gastric ulcers was comparatively futile. That carcinomas occasionally actually arise on ulcer margins is fairly certain, but probably they most commonly have their origin in the atrophies, disorganizations and reparative hyperplasias which represent the residuals of many previous ulcers.

Many logical objections may be raised against the theories which have just been proposed. The first and most important question concerns the mucosal collections of lymphocytes, which I have assumed represent the residual (or the continuation) of inflammatory processes. This assumption, I am compelled to admit, is insufficiently supported by the facts at my command. The true significance of lymphocytes, whether in the blood stream, bone marrow, lymph nodes or follicles, under normal conditions is but little understood. Not much more is known about their meaning in pathologic processes. Their constant presence in the delayed repair of almost all inflammations and wounds has led most pathologists to assume that when lymphocytes are seen in abnormal locations or abnormal numbers some form of chronic inflammation is indicated. When such collections of lymphocytes are accompanied by other evidences of inflammation this assumption would seem to be confirmed, although whether the lymphocytes wander in ("infiltrate") or are formed in situ from some form of connective tissue cells, and why they are there at all is not known. But when collections of lymphocytes are found where lymphocytes are not normally present and no other inflammatory phenomena can be identified the problem becomes more complex. The other day I examined sections from an 18 year old boy whose death was due to diabetes. The mucosa was mottled by numerous large collections of lymphocytes. Did they represent the residual of previous innumerable ulcers and, if so, how could they collect in

Fig 6—Cyst in the mucosa of the stomach in case of carcinoma stained with hematoxylin and eosin (X56)

such large numbers with scarcely no other evidences of disorganization? It strains one's imagination, I must confess. But suppose for the sake of argument that some other influence, certainly not known, accounts for these lymphocytes. Does their mere presence denote chronic gastritis? I doubt it and still insist that lymphocytes are a part of the incompletely healed ulcer complex, even if they also may occur from other causes.

<sup>4</sup> Stoerk Oskar Ueber Gastritis chronica. Wien klin Wchnschr 35 855 860 (Nov 2) 1922

When the usual discussions dealing with the various causes of gastric ulcers are reviewed, my assumption meets with further objections. One school mentions bacterial infection either directly invading the mucosa or carried to the stomach wall by the blood stream. Another view considers embolism or thrombosis with consequent infarction of the mucous membrane as the fundamental lesion behind many gastric ulcers. Direct attack by the gastric juice or ingested corrosive agents has also been considered. It must be granted that at times each of these "causes" may operate in the production of gastric ulcers, but even in such (to me) unusual conditions the lesion is accompanied by hemorrhage and necrosis. Once the ulcer is produced, by whatever mechanism, when healing is in any respect incomplete, the residual deformities which I have described must result.<sup>5</sup> I am still of the opinion that the most frequent cause of ulcer of the stomach is hemorrhage from the capillaries of the mucosa, that many, perhaps most, of these ulcers so produced heal perfectly, but that a few in most persons and many in some heal

Fig. 7—Glands in the gastric submucosa stained with hematoxylin and eosin slightly reduced from a photomicrograph with a magnification of 60 diameters

less completely and leave persisting the various disorganizations which I have described. When the healing is so imperfect that the surface layer defect still remains, naturally a more or less "chronic ulcer" is a correct designation.

While admittedly, experimentally produced ulcers in animals do not necessarily parallel in clinical and pathologic manifestations the ulcers found in man, nevertheless the same physical reactions should occur in the development subsidence and residuals of the lesions in the two instances. It was therefore particularly important to examine the stomachs of dogs in which ulcers had been produced by administration of cinchophen after the method described by Stalker, Bollman and Mann.<sup>6</sup> Studies of microscopic sections of these stomachs revealed in all essential details the same pictures which have been found and described so frequently in human stomachs.

We are now in position to consider more critically the meaning (or lack of meaning) of the words "chronic

gastritis." If we assume that the residual lesions which accompany the healing of certain gastric ulcers represent diminishing or receding processes, terms denoting chronic inflammation may not properly be employed. Unfortunately there are no appropriate names to denote the lesion which is in the stage of being healed but in which there will not be complete restoration of the affected part. "Unresolved" gastritis might be used but the word "resolution" usually refers to purely exudative inflammations. Even if it is conceded that the term "chronic gastritis" may be employed to denote the conditions under discussion, at best it would only have a significance for the pathologic anatomist and would in no way be useful to the clinician for correlation purposes.

Therefore I am proposing that the unqualified designation "chronic gastritis" should not be employed to represent a separate entity either clinical or pathologic. "Ulcerative gastritis" either "acute" or "chronic" is an eminently appropriate term when ulcers are present. If "syphilitic gastritis" or "tuberculous gastritis" or other specific lesion is diagnosed, the qualifying words are clearly indicated. But for the various conditions which I maintain represent the results of an imperfectly restored "ulcerative gastritis" after the ulcer surface has been covered with epithelium, I am forced to suggest the rather awkward designation "residual of ulcerative gastritis" with atrophy, hyperplasia or scar formation as the case may be.

It is strongly urged also that the clinician should not use the almost meaningless term chronic gastritis. Instead he should employ names which have a definite significance such as atrophy of gastric mucosa, hyperplasia of gastric mucosa (localized or polypoid), ulcerative gastritis, syphilitic gastritis, tuberculous gastritis, alcoholic gastritis, atony of stomach or achlorhydria. Even the old fashioned word dyspepsia, rather discredited at the present time has more clearcut clinical distinction than other more popular substitutes.

It has not been my purpose to cover the entire pathology of the stomach. Lesions or dystrophies of the central or local nervous mechanisms may profoundly affect the motor and secretory activities of the organ and play a prominent part in clinical judgments. Primary and secondary anemias, passive and active congestions, high temperatures and diseases of neighboring viscera may exert definite influences on gastric functions. Lastly, it is quite probable that in the future various abnormal amounts or lack of hormones or vitamins may be proved to determine certain gastric lesions just as to an increasing degree they are assigned an important role in the alterations of other structures of the animal body.

#### CONCLUSIONS

- 1 The most frequent lesion of the gastric mucosa is capillary hemorrhage.
- 2 These hemorrhages result in necrosis and ulcer formation.
- 3 Most of these ulcers, more in some cases than in others, result in complete restitution of the stomach lining and are without recognizable clinical phenomena.
- 4 Some ulcers are sufficiently severe to leave residual lesions even when the outer epithelial lining is restored and the ulcer as such disappears.
- 5 These residual lesions are collections of lymphocytes, irregular thickening and fibrosis of the muscularis mucosae, atrophy of the specialized gastric cells and

<sup>5</sup> By incomplete healing, I do not mean any residual defect in the superficial layer of mucosal cells. These cells may cover the healing ulcer but the underlying elements may or may not be perfectly restored.

<sup>6</sup> Stalker, L. K., Bollman, J. L. and Mann, F. C. Experimental Peptic Ulcer Produced by Cinchophen. Methods of Production, the Effect of a Mechanical Irritant and the Life History of the Ulcer. Arch. Surg. 35: 290-308 (Aug.) 1937.

more or less hyperplasia of the mucous glandular cells with varying degrees of disorganization of the mucous glands

6 The hyperplasia of the mucous glands may have some relation to the development of carcinoma

7 Some ulcers persist, for unknown reasons, and become chronic

8 It is suggested that lack of mucus may be one factor in delaying the healing of gastric ulcers, and furthermore that mucus production itself may in some manner be under cerebral control

9 Experimentally produced ulcers in the stomachs of dogs present pictures similar to those studied in human stomachs

10 The residual lesions of ulcerative gastritis are the most frequent pathologic changes seen in the stomach wall

11 The designation "chronic gastritis" has no clear significance and should not be used without qualifying adjectives, for example "chronic ulcerative gastritis"

12 Clinicians should use only terms which have a definite clinical and pathologic significance

#### ABSTRACT OF DISCUSSION

DR ALVIN FORD, Los Angeles Might I ask Dr Carlson whether he found in the man into whose stomach he looked for many years any of these ulcers and hemorrhages?

DR A J CARLSON, Chicago I didn't intend to say anything at this time, but being asked I wish first of all to remark that it is a pleasure to listen to a pathologist whose reasoning hasn't become pathologic. The relation of gastric lesions to subjective symptoms is certainly complicated. Yes, I looked into the stomach of Mr Vlcek almost every week for thirteen years before he developed cancer in the old scar in the gullet. Dr Beaumont was a good observer. Anything that Dr William Beaumont saw and described has stood the test of time. Now, my edition of Alexis St Martin wasn't quite as bibulous as Beaumont's, and I didn't have so many alcoholic conditions. But I saw from time to time in Vlcek's stomach virtually all that Beaumont observed in St Martin. And I saw another thing. That this man could have severe symptoms of gastric pain, with all the mucosa that I could see perfectly normal. I remember one time I had a balloon in his stomach. This didn't produce any pain. I have had balloons in my own stomach. But at that time Vlcek had a spasm of the stomach lasting twenty minutes, and as he was sitting there cold sweat ran down his forehead and he was saying "Carlson, I can't stand it, I can't stand it." I said "You have got to, I want to see how long this is going to last." There might have been something beyond the pylorus which I couldn't see. There might have been something in the extreme antrum that I couldn't see, but the rest of the gastric mucosa was perfectly normal. An extreme spasm of a healthy organ gave rise to something that is not so different from the extreme spasm in a healthy uterus or a charleyhorse in a healthy muscle. I should like to know why some of these extensive superficial erosions sometimes give rise to a sensation of not definitely localized pain but discomfort. One just doesn't feel right. One of the most interesting things described here by Dr Robertson is the "occlusions," in other words, gastric glands that have no openings. Did you follow them from end to end? Do it, please, because that is very important. If you are right we have here something like those dermoid cysts, probably with distention with the surface of the mucosa perfectly normal. The sensory nerves in the gastric mucosa, particularly those that refer to pain and reflexes are probably stimulated by tension.

DR H E ROBERTSON, Rochester, Minn I have recently been interested in several papers published by gastro-enterologists who have been observing stomachs with the gastroscope. They are now seeing under difficult circumstances the same thing that Dr Beaumont and Dr Carlson have seen with their own eyes, and under much better conditions. The interesting

thing is the frequency of these hemorrhages observed by these people. The thing that I feel they have missed is the fact that ulcers are the result of the hemorrhages that they see, most of them healing completely. We all have them frequently, probably every single day of our lives, and when for some reason or other they don't heal, then in a few of us comes possibly the real ulcer. It isn't. What causes the ulcers? The question is "Why don't some of the ulcers which we have from time to time heal?"

#### THE USE OF FREE FULL THICKNESS SKIN GRAFTS

J EASTMAN SHEEHAN, M D

NEW YORK

In every case in which skin is to be replaced, consideration is to be given to all the conditions existing, so that choice may be made of the best form of graft or flap for the particular repair. Thus, when the defect to be covered is on the face, a primary consideration is to ensure that the new skin will conform to its surroundings in texture, in surface level and in coloration and will incorporate imperceptibly with the skin adjoining.

While these requisites might be found in a pedicle flap raised from an adjoining area, the difficulty is that this method produces and leaves a visible disfigurement. The thin epidermic graft will not do either. It is too thin to maintain the surface level of its surroundings, and it tends to take on a brownish tint that does not conform to the rest of the face. The tubed pedicle flap, valuable as it is in some situations, undergoes changes in its fat and fibrous tissues in the period after it is tubed, which operate against its conforming to the new surroundings, in texture, elevation and motility.

The preference, therefore, in conditions that are otherwise favorable is for the free full thickness skin graft, which has none of these disadvantages. What for a long time militated against its selection was the uncertainty of successful application.

Not so long ago, a 50 per cent success was about all that could be expected. At present, while it might be oversanguine to claim a hundred per cent success, anything below that may be due to some exceptional and undisclosed condition.

To what can this improvement be attributed?

The answer goes in part to the conditions prevailing when the graft is taken, in part to the handling and care of the graft in the process of replacement, in part to the state of the base on which it is applied and in part to the concern shown for the graft after it has been applied.

1 The skin should be in a healthy state. This applies not alone to the immediate vicinity of the area from which the graft is to be taken but to the body generally. Some of the deterrent conditions are obvious, as disease. Some are danger signals, as pimples, which suggest delay until improvement has been effected. There may be a concealed infection, of which the skin itself gives no sign but which will prove disastrous when it is declared in the weakened condition of the cells after they have been deprived of their normal sustenance. Two highly useful tests can be applied by way of check on such unknown factors. One is the Schilling test. In the presence of infectious processes, immature neutrophils enter the circulation in increased

numbers. As compared with a ratio of 10 in normal persons and of 25 in slight infection, there may be indicated an index of 50, 75 or more. By any such indication of infection the operator is put definitely on warning and must postpone until the index is suitably lowered. Again, as the success of the graft is to be attained only when the bed on which it is placed is at its best, and as oozing will impair or destroy this condition, it is important to know what the probabilities are in this particular. Where, for example, the blood platelet count is much too low, such oozing is to be apprehended, with consequent danger to the success of the graft, as a whole or in spots. In presence of these or any other warnings against haste, delay is instituted to allow of the conditions being corrected.

2 The graft area itself equally demands respect. It has a normal oxygen and sulfur content, and if either is below normal the impaired vitality of the cells will be reflected when the graft is transferred. Biochemical tests for these contents have been devised, and if the results are unsatisfactory there is reason for delay until correction is effected. Moreover, it has been found that these contents are reduced in the process of cleansing and preparing the area for operation. The cleansing for this reason, is best done the night before the operation to allow time for recovery of the oxygen content. The skin is scrubbed with soap and water further cleansed with sulfuric ether and left covered with antiseptic gauze overnight. The use of antiseptics with a view to bacterial destruction on and within the apertures of the skin has not survived trial and error. The most successful of them as germicides have been found to set up conditions difficult to deal with and in any event more importance attaches to having the skin in a healthy condition than to precaution against germs of infection in a skin not at its best.

3 A dry base at the defect area is absolutely essential. There must be close adherence of the graft to the base, and this there cannot be if there is oozing and consequent blood clots, even the smallest of which will be destructive as to the space it occupies. Obviously, the vessels in the base must have attention. If any are to be tied it must be by suture threads that will not promote infection. The finest Deknatel silk is used. Precautions having been taken against oozing by reason of conditions disclosed by the count of the blood platelets, it may be desirable to obtain further assurance by irradiation of the spleen by roentgen rays in amounts of from one-tenth to one-fifth erythema dose. About twenty-four hours after irradiation the coagulation time of the blood is gradually materially reduced, a fact helpful to the restoration of the graft. Intravenous injection of calcium or a hemostatic preparation the day before operation may be of additional advantage.

4 In taking the graft, the lines of skin tension should be respected. The graft should be cut without bevels at the edges and be a little less than will cover the defect, as it is well to have the graft on stretch a little when it is sutured in place. There is no need for rough handling. The graft can be gently transferred by threads that are to serve as anchor sutures. It should not be washed in saline or other solution. Its own serums have the double utility of temporarily countering infection and of assuring adhesion between the graft and the base. The suturing in place must be done with great patience and with care to ensure that the resultant scar at the wound edges will have the least attainable visibility.

5 With all this done, there is still to consider the factors that govern the restoration of life and function in the graft skin. With a sound, viable graft, on a dry bed, that phase begins on skin that has been detached from the normal agencies that supply life to the cells. There are two influences that make for recuperation from this moribund condition. One is the infiltration of minute vessels from the base into the corium, the other is the nourishment that may be derived by the cells from the pervading lymph. Vascular infiltration is a slow process, and if the very lowest part of the skin is transferred, as was formerly the practice, it takes time for the vessels to reach the tissues of the subpapillary layer. Whereas the cells of the epidermis are not sustained by vessels but are nourished by the lymph from the base on which they are set, when it can be conveyed to them, the connective tissues of the corium must have sustenance from vessels to which they are accustomed. To mitigate the delays, the lowest, densest subcutaneous layer is removed. Whether it is that this results in more rapid infiltration of the remainder of the corium or that the subpapillary area shares with the epidermis the sustenance derived from the lymph fluid, or both, the fact is that restoration proceeds with greater rapidity and with increased assurance when this lowest stratum of the skin is discarded. To this may be attributed much of the recent advance in the ratio of success.

With the graft in place, concern is for the proper pressure and, no less important, for immobility. One of the first things learned about the graft was that either too much or too little pressure would cause it to fall. With too much, the infiltration of vessels was impeded, with too little, the adherence of graft to base was disturbed. Ferris Smith, arguing from the circumstance that infiltration of vessels from the base to the graft is the critical stage, found a mean of pressure related to that of the blood. This provided a practical answer to the problem of too much or too little. The method of applying the pressure varies. It can be by pressure bags, judiciously inflated, or it can be on smaller, well situated areas, by means of a mold of stent. In either case, to insure immobility is a desideratum. A mold, for example, may be immobilized on the cheek by means of an outer frame of celluloid (Coelst), so placed as to relieve the mold and graft of adjacent strains. In other instances, changes in contour may present difficulties, which can, however, be overcome. In either case, motion must be prohibited during several days. For example, when replacement is in the neighborhood of the mouth, no food or drink is allowed to enter by mouth, a Nelaton tube is introduced through the nose for purposes of feeding.

Finally, the patient must be kept quiet. There is some sympathetic reaction to operation, and the consequent irritability should be allayed.

Two capsules of thiamin chloride consisting of 2,000 international units given daily, with nicotinic acid in 1 grain (0.065 Gm.) doses, have been found to give relief. When there is evidence of shock toxemia, food is stopped and intravenous dextrose solution given. The essential quiet can be further induced, of course, by personal attention and the confidence it inspires.

The sum of it all is that knowledge of the life of the skin, and respect for its demands in the stress to which it is exposed by transfer, has changed the whole outlook on the use of the free full thickness skin graft.

With all the precautions that can be taken, and with the full thickness skin graft thus made practical as

cover for larger and larger areas and for greater variety of reparative recourse, it is not to be inferred that complete success is automatically assured. On the contrary, it must be watched continuously and danger signals should receive prompt attention. Of these the first is rise of temperature, which may mean infection in the graft. One is not to assume that the high temperature is of this origin. It may be located quite otherwise, thus averting the mischief that might ensue on too hasty removal of the bandages. But if high temperature is accompanied by discharge at the graft area and by odor that tends to become foul the graft is uncovered and remedial measures are promptly taken. When there are none of these indications of infection, the bandages are usually left for about three weeks. By that time the preliminary organization usually is definitely established.

833 Fifth Avenue

#### ABSTRACT OF DISCUSSION

DR GEORGE W. PIERCE, San Francisco. There is no doubt that full thickness skin grafts are of great value in reconstruction surgery. As compared with the success of such types of grafts twenty-five years ago there has been a tremendous advance and the advance has been the result of the successful use of these grafts through attention to the minutiae of detail. I think that hemorrhage looms larger as a deterrent of success than any other one factor. I am glad that Dr. Sheehan called attention to the use of soap and water in preparation. There is one point I wish to mention in regard to these free grafts, and that is that in my experience and in cases that I have seen in different medical centers I have noted pigmentation of these free grafts occurring in at least 20 per cent and in such marked degree in from 5 to 8 per cent that for use on the face it almost precludes promise to the patient that the color will be the same. As to the splinting of these grafts, I prefer physiologic solution of sodium chloride, gauze, marine sponge and finally a bandage which is made by cutting stockinet on the bias. This provides an elastic pressure which is necessary for a period of three weeks on these grafts.

DR H. L. D. KIRKHAM, Houston, Texas. The principles as laid down by Dr. Sheehan for the use of free grafts are the same no matter whether they are a full thickness, a split or the so called thin Thiersch graft, that is to say, the principles of preparation and condition, the bed pressure, the cleanliness and good condition of the skin that is taken and also the area it is being taken from. I cannot quite follow him in his estimation of oxygen and sulfur, why that should be more important in a full thickness than in any other type of graft and certainly I believe that the results in the percentage of takes, at least in my hands, of full thickness as compared with the other types of free graft are not as good. Then too it is always possible in the use of any of these plastic procedures that the personal equation of the surgeon enters largely into it and that method within normal and proper limits which meets the best and most uniform success in an individual's hands should be his method of choice. I was glad to hear Dr. Pierce mention the question of pigmentation in free grafts. Probably I can speak a little more feelingly about the matter, coming from the South with a large Negro population and a large Mexican population—in other words, people with pigmented skins. The development of pigment in the free graft is so prevalent in those races that I would no more dare think of putting a free graft to a white Negro's face or exposed part without warning him ahead of time that it was not a possibility but a probability that the graft would almost, as in some instances it does, get coal black, whereas the rest of his skin is white. Dr. Sheehan gave, as the signs or symptoms of trouble with his graft, high temperature and a foul discharge. He then recommended that if those appear, suitable remedial measures must be instituted. My experience in using these free grafts is very like taking a kodak picture. After one has used the proper shutters and all the proper factors that go with it, it then becomes, as the Negro said, a "question of you either you is or you ain't." And

if the graft "ain't," I don't know of any remedial measure one can take to bring it back to life after it has once died, and I would like to ask what remedial measures Dr. Sheehan uses when the symptoms he mentions appear.

DR J. EASTMAN SHEEHAN, New York. Pigmented cells take rise at the level of the epithelial layers and normally are carried off as they descend. In the epidermic and intermediate grafts, when cut and transferred, the avenues of descent are impaired, and the tendency in the thin grafts is for the melanotic cells to group and so affect coloration. This applies to white skin, with which I usually have to deal. The comments regarding Oriental and Negro coloration suggest that there may be different problems, in the incidence of pigmentation, in these categories. My primary problem is so to simplify the procedures that the repair can be effected without producing disfigurement. This can be done, and done best, even on large areas, by recourse to this free full thickness graft. The point about oxygen and sulfur content is that if they are below par the success of the graft is less assured. Both are important elements of the skin, and, since their adequacy can be determined, impairment of the normal should be guarded against, and deficiency should be rectified before operation. It has not been made clear to Dr. Kirkham what is meant by resort to remedial measures. The enemy, of course, is infection, and infection may be detected beneath the bandage. Ordinarily, the longer the bandage can remain the better for the graft. But a bandage that covers infection obviously should be removed, and since one does not want to remove it, one watches for signs that one must. Rise of temperature is a danger signal, but if its origin is located elsewhere there is no need to remove the bandage. If there are discharge and odor, the bandage comes off, and I proceed to deal with the infection. I need not go into the measures that are needed to control infection. They are peremptory, whether they succeed in saving the whole of the graft or only part of it.

#### THE CLIMATIC TREATMENT OF HAY FEVER AND ASTHMA

WITH SPECIAL REFERENCE TO FLORIDA

FRANK C. METZGER, M.D.

TAMPA, FLA.

The mirage of climate as a curative agent for disease has long been pursued both by physicians and by the public. Its lure has had particular appeal in the treatment of chronic ills such as tuberculosis, hay fever and asthma, but the results of climatic change have all too often been disappointing, certainly so far as asthma and hay fever are concerned.

The peninsula of Florida, uniquely situated as it is, has a climate differing radically from that of most of the United States and Canada. Consequently its subtropical setting invites countless sufferers from all walks of life who seek climatic relief from hay fever and asthma. Those who come to the state for this purpose fall naturally into three groups: (1) those who obtain no relief, (2) those who become worse in the new climate or environment and (3) those who obtain complete or partial relief.

In a practice in Florida confined exclusively for years to the treatment of the allergic diseases, there have come under my observation too small a number of patients who have found complete or partial relief through climatic change to warrant this form of treatment. In this group, group 3, a careful study of the history of the patient often discloses that relief has resulted from accidental removal from the source of trouble, or it transpires that some causative factor has been discovered and eliminated that could as easily have been removed at home. Scientifically, to increase the number of persons who obtain complete or partial

relief through climatic change or other agency is a primary objective. From the humanitarian standpoint, as worthy an objective is to recognize the cases in which relief resulting from change of climate is not to be expected, thus sparing the patient unnecessary change.

The physician over the land who glibly advises change to a fancied climatic utopia is spared the problems his injudicious counsel frequently creates for his colleagues and the communities of the state or region for which he unwittingly makes fallacious claims. Nor is he confronted with the stark human tragedy that often follows in the wake of ill advised change. Not infrequently whole families, greatly to their disadvantage, are torn from their financial and social roots in the interest of the individual sufferer. The present economic situation, with its widespread unemployment, increases the difficulties and hazards of such change for many persons or families already handicapped by illness.

Before change of climate may be discreetly advised for sufferers from hay fever and asthma, a knowledge of two things is necessary. First, the allergen or allergens that precipitate the patient's trouble must be found. Fortunately the newer concepts of allergy, with the means and methods now available through cutaneous tests, histories, eliminative diets and other procedures, make possible the determination of the offending substances in the large majority of cases. In the second place it is necessary to know in what climate or place the allergens affecting the person in question do not exist, exist in small amounts or are easily avoidable.

The clinical observations, results of experimentation and conclusions here set forth are designed to aid the general practitioner in particular, and the allergist as well, in disseminating information regarding the occurrence and distribution of allergens in Florida. Since the allergens causing hay fever are, in general, able to cause asthma also, the statements here made regarding the one are applicable also to the other. As certain pollens are present throughout the year in this state, the term *pollinosis* is used to designate the type of hay fever in which pollen predominates as a causative factor, and the term *allergic rhinitis* is applied to those types in which other allergens are the offenders.

*Pollinosis* occurred in 24 per cent and *allergic rhinitis* in 76 per cent of the patients coming under my observation who were year round residents of Florida, including Key West, and of Cuba. In the practice of allergists in the more northerly states, such as, for example, Drs. Milton B. Cohen<sup>1</sup> of Cleveland and Tell Nelson<sup>1</sup> of Evanston, Ill., these percentages were almost completely reversed. The reason for the relatively few cases of *pollinosis* apparently lies chiefly in the fact that pollen concentrations are not nearly so great in this state as in the Northern, Eastern and Midwestern states.

#### POLLINOSIS

In considering the pollens it is well to divide the state roughly in half, placing the dividing line from Brooksville near the west coast to St. Augustine on the east coast. The climate, the soil and, consequently, the flora and the occupations differ greatly in the northern farming section from those in the southern portion, with its truck gardening and cultivation of citrus fruit.

Ragweed, grass and trees furnish the offending pollens of most importance. *Ambrosia elatior*, or dwarf

ragweed, is the only variety of ragweed having clinical significance. Present in the state for many years in small amounts, it has increased greatly since 1925 in the wake of new road building and widening areas under cultivation. Many factors enter into its pollination time and the concentration of its pollen in the air. In coastal cities alternating sea and land breezes cause the air-borne concentration to fluctuate. Pollen slides exposed in Miami Beach and in downtown Miami rarely showed ragweed pollen granules, but a series of slides exposed in June 1935 at Coral Gables, 7 miles west of Miami, showed as many as 1,010 granules of ragweed per cubic yard a day. Miami's prevailing east wind accounts for this condition, at least in large measure. The west coast has no prevailing wind, and, in consequence, the pollen count varies with the alternating sea and land breezes.

Throughout the state the season of ragweed pollination varies greatly. At Ellenton, 35 miles south of Tampa, it begins as early as May 10. There, where the big spring crop is tomatoes, and a little farther south on the truck and celery farms east of Sarasota, heavy fertilization of the fields, with consequent fertilization of the ragweed bordering them, seems to be the only explanation of the early pollination in that locality. At Sanford, in the central part of the state, where celery has long been intensively cultivated, ragweed grows in abundance, and pollination begins early and continues over a long period.

Ragweed in Tampa attains a height of from 2 to 4 feet about May 20 and appears to be ready to burst into full bloom, but appreciable amounts of its pollen are not found on exposed slides before the middle of August. The appearance of clinical symptoms in patients sensitized to it coincides with this date. Close to the Gulf of Mexico but without a prevailing west wind, Tampa has a fairly steady pollen count from day to day, the average in 1936 having been 11 granules per cubic yard a day and the maximum 59 granules. Without frosts to kill the weed, it dies out gradually and is gone by the middle of November. The situation is practically the same in St. Petersburg.

Grass pollens are so nearly alike microscopically that their identification on exposed slides is seldom attempted. The many wild or native grasses of Florida produce little pollen, and the heavy producers of pollen, i. e., the cultivated grasses raised for pasturage, such as timothy, are practically nonexistent. The Bermuda, St. Augustine and centipede grasses, the three cultivated grasses used chiefly for lawns, are prolific producers of pollen, especially the Bermuda grass, its pollen containing a large amount of the protein excitant of *pollinosis*. Frosts or freezes rarely kill these grasses and they are in a state of pollination every month of the year, having seasonal peaks. The season of heaviest pollination usually begins late in February and continues through March and April, varying with the amount of rainfall, and there occurs a second peak of production during the summer rainy season in June or early July. Actually, the grass pollen count even in these peak seasons rarely exceeds 14 granules per cubic yard a day and varies from 2 to 7 granules throughout most of the other months. This concentration is in contrast to the grass pollen count of Cincinnati, for example, which runs commonly from 85 to 100 granules per cubic yard a day in April and May. In southern Florida, therefore, patients highly sensitized to grass pollen require treatment throughout the year. Those with a relatively high tolerance

<sup>1</sup> Personal communication to the author.

complain of symptoms only from March through September, but those with a low tolerance have trouble all the year

There is another group of patients, in whom pollen from grasses may act as a contributing cause and symptoms are present only in winter. Unless such patients are appropriately treated for this secondary factor, relief will not be obtained

Next in importance are the trees. The citrus trees and the various kinds of blossoming palm trees over the state rarely cause trouble, for they are largely insect pollinated. The pollen of the long leaf pine, the tree most commonly found in Florida, is generally conceded to have little or none of the protein excitant of hay fever. The cypress tree, plentiful in growth and having its season of pollination in January and February, is also negligible as a causative agent. The eucalyptus tree is practically never found except in towns and cities, usually in the wake of women's garden clubs. Its pollen is a source of trouble, as a rule in February or March. The pecan tree is so seldom encountered in southern Florida that it constitutes only a local problem, but in the far northern section of the state, where pecan groves are numerous, its pollen is troublesome. Certain species of oak are common to the state. A rank growth of scrub oak, mostly white and burr oak, like that covering the uncultivated lands of the northern section, occurs sporadically in the southern part, but the large oaks so familiar to the northern scene are seldom found there. The live oak and the water oak are found in both sections. They are heavy producers of pollen, but even trees of the same species growing close together may differ as much as a month in the time of their pollination. Consequently the season for oak may last six or eight weeks, and it starts as early as January 20 if there has been considerable rain and warm weather immediately preceding. The pollen count for oak this year in and around Tampa ranged as high as 240 granules per cubic yard a day.

The Australian pine, known botanically as *Casuarina*, is a new tree now being widely grown in the towns and on the beaches of southern Florida for shade. Despite its name, it is not a conifer. November is the season of its heaviest pollination. Many of my patients have been tested with solutions of its pollen, but positive results have not yet been obtained. Mr. O. C. Durham, chief botanist of Abbott Laboratories, stated that there is "no reason why its pollen should not cause trouble."

The pollen counts herein reported were made with the assistance of the Florida State Board of Health and checked by Mr. Durham. Recently Mr. Durham made counts of the pollen of the bayberry bushes and found an appreciable amount in the air. The season for their pollination is in March or April. "Spanish moss," often inquired about, is a true flowering plant, blooming in May and June and classified as *Dendropogon usneoides*. My experiments,<sup>2</sup> both with the pollen and with the dried plant, gave only negative results.

Although the variety of plants in the chenopod, composite and amaranth groups is large, such plants are but minor sources of trouble, and only a few cases have come under my observation in which pollens from them were contributing factors. Dog fennel is fairly abundant. Pigweed, or spiny amaranth, grows to great height and is not uncommon. The common plantain is not found in Florida. The wide variety of shrubs,

plants and trees introduced from the North, largely for purposes of landscape gardening, have no general importance.

#### ALLERGIC RHINITIS

According to my records, the offending inhalant allergens in allergic rhinitis in Florida are, in the order of their importance, house dust, orris root, feathers, animal inhalants and occupational dusts. House dust, the chief offender, requires special comment. The observation, over a period of years, that certain resident patients were relieved of symptoms when they visited Northern states or Cuba and that many patients from the North, sent by their physicians to take the "climate cure," became worse immediately or shortly after arrival, led to a survey which showed that in these cases, with few exceptions, housedust was the predominant factor. To test whether the unknown offending allergen of house dust was present in greater amount in the dust of Florida than elsewhere, specimens of an extract of house dust from homes in the state were sent to Drs. Milton B. Cohen of Cleveland, Tell Nelson of Evanston, Ill., Harry L. Huber of Chicago and Matthew Walzer of Brooklyn. After these physicians had made comparative tests and given clinical treatment with this extract to patients proved sensitized to dust, Drs. Cohen, Nelson and Huber<sup>1</sup> reported that the extract of house dust from Florida was undoubtedly more concentrated than that taken from their local sources by the same method. After making comparative cutaneous tests, Dr. Walzer<sup>1</sup> did not concur in this conclusion. Certain it is that, clinically, the percentage of cases in which house dust assumes a foremost place is larger in my practice than in the practice of the Northern allergists<sup>3</sup> with whom I have consulted. The explanation of the relief experienced by patients sensitive to house dust who visited in Cuba probably lies in the relative lack of sources of house dust in a land of open windows, tiled floors, little overstuffed furniture and few carpets and window draperies.

Second in importance is orris root. This substance should in future cause less trouble, as most manufacturers of cosmetics and talcum powders have ceased to use it as an ingredient of their products.

Feathers, ranking third, need no comment.

The explanation for the dearth of cases of allergic rhinitis caused by animal inhalants is not too apparent. Certainly there are as many household pets in Florida as elsewhere, but living conditions in the mild climate tend to keep both man and animal more in the open and therefore less in intimate contact. Also there are relatively few farms, with their horses, mules, cows, pigs and chickens.

Occupational dust is infrequently a cause of allergic rhinitis in Florida. The comparatively few manufacturing plants in the state operate under airy conditions and with windows open at all seasons.

Rarely does a case of allergic rhinitis come under my observation in which sensitivity to food is not a factor. The foods producing symptoms of themselves or complicating inhalant factors differ somewhat in Florida from those listed elsewhere.<sup>4</sup> In a series of 500 of my cases, foods in the order of the frequency with which they produced sensitivity were oranges and other citrus fruit, condiments, sea foods (both fish and

shell fish), milk, wheat, rice, eggs and vegetables. Winter visitors find oranges astonishingly cheap, and both temporary and permanent residents, rich and poor alike, consume them in large quantities. Fish and shell fish also constitute a staple article of diet, for they are fresh, cheap and plentiful all the year. Too, they call for condiments. That these foods take precedence among offending foods favors the hypothesis that the allergic person, having a tendency to become sensitive, naturally becomes sensitized to the foods he eats in excess or with greatest frequency.

In general, patients with allergic rhinitis respond less readily to treatment than do those with pollinosis. A large number require close cooperation between the allergist and the rhinologist. The situation varies little over the state, for slight difference is noted between patients living in Jacksonville, Gainesville and Pensacola and those living in Tampa, Miami and Fort Myers.

#### NONSPECIFIC AND PSYCHIC FACTORS

Nonspecific causes, thermal, chemical, neurogenic and physical, are not well understood and their mode of action is uncertain, but when they are a large factor the patient should find the climate of Florida ideal. Smoke and soot are practically absent from the air. The temperature is of the marine type, and the sudden violent changes that appear to affect allergic persons more than the degree of heat or cold are unusual. Patients whose condition is complicated by a cough with profuse expectoration, bronchiectasis or sinusitis are usually benefited by sunshine and warm weather.<sup>5</sup> It is well known that Florida has some 600 more hours of sunshine annually than most Northern states.

The neurogenic or psychic element presents an unexplained vagary to be reckoned with in the treatment of allergic diseases. Changing physicians, taking a new remedy or starting a new procedure, regardless of the therapeutic value may relieve a patient of a prolonged spell of asthma, doubtless because of faith in that which reputedly cured a relative or a friend. Accordingly, so radical a procedure as a change of climate, backed by the strong suggestion of the physician that benefits will result, should in some cases turn the neurogenic factor to favorable account, at least temporarily and perhaps permanently if the new climate and environment are wisely chosen with a view to meeting the patient's other needs. On the other hand, fear of being away from home or worry over the expense involved may cause an asthmatic patient to become worse regardless of the absence or presence of specific allergens in the new climate. The results of change of climate may not always, therefore, be interpreted solely on the basis of the distribution of specific allergens.

#### SUMMARY

Investigations have shown that in Florida the amount of air-borne pollen is small, its variety limited and its season practically all the year. Only the pollens of ragweed, grass and oak are of practical importance. The concentration of ragweed pollen is very small, and clinical observation warrants the conclusion that most persons sensitized to this allergen are free from symptoms in Florida. The east coast section, the nearer the beach the better, should afford freedom from symptoms to all sufferers from the pollen of ragweed, the midstate section and the west coast are suited to all

except those highly sensitized to this pollen. With the exception of patients sensitized to oak or highly sensitized to grass pollen, persons with pollinosis should do well in the state. Those who fear that Florida is unbearably hot during the months in which the pollen to which they are sensitized is in the air in the North or Midwest need only consult the records of the United States Weather Bureau.

Until the nature of the allergen in house dust is identified, it appears wise from clinical observations to advise asthmatic patients sensitized predominantly to house dust not to take up residence in Florida, especially in winter. Other inhalants causing allergic rhinitis are no more troublesome in Florida than elsewhere, and some such as animal inhalants and occupational dust, much less so.

Sensitivity to food is almost invariably a primary or a contributing factor in allergic rhinitis, and in my study of 500 cases I observed that the chief offending foods differed somewhat from those listed by other investigators. My observations tended to support the hypothesis that persons with a tendency to food sensitivity become sensitized to foods eaten in excess. Thus, the informed patient, on coming to Florida, may avoid the possible hazards of such major offenders as citrus fruit and sea foods by not indulging excessively in them.

In selected cases in which nonspecific causes are of importance, the climate of Florida may be of particular benefit. The psychic element, however, in the treatment of both asthma and hay fever may render difficult the interpretation of results.

The problem of the allergic patient is highly individual. The physician who advises change of climate without knowing the sensitivities of the particular patient, and without ascertaining the distribution of allergens and the general suitability of the climate suggested, fails to do the patient full justice. In recommending change he need be guided only by the dominant factors characterizing the patient's history, and he may obtain information about climate for the asking. Likewise, the layman who, at great mental or financial risk, perhaps, seeks a "cure" in Florida or elsewhere without securing competent professional advice and accurate information, takes a long, long chance on following nought but the lure of a climatic mirage.

**Cells Which Secrete Hydrochloric Acid**—One of Bernard's often quoted discoveries in the field of digestion is his location of the glands which secrete hydrochloric acid. The date of the experiment was January 1850. Into the vein of a fasting rabbit he injected a solution of a soluble salt of iron, the lactate, then followed it with a solution of potassium prussate. In the presence of acid these two salts form prussian blue, the vivid color of which is readily detectable in very small quantities. The animal was killed three quarters of an hour later and an autopsy performed. In the superficial layer of mucus covering the surface of the stomach, especially along the lesser curvature, the blue color was to be seen. In his comment on this experiment Bernard stated that it not only showed the glands which secrete gastric juice since this product is always acid, but it also showed that the acid did not exist within the glands themselves but that the gastric juice only acquired its acid properties outside the gland when mixed with the other liquids of the stomach. This deduction was correct and the chief additional fact which has come to light since Bernard's day regarding the secretion of gastric juice is that it does not come from one single kind of gland, the acid comes from one kind of cell and the pepsin from another—Olmsted, J. M. D. Claude Bernard, Physiologist, New York, Harper & Bros., 1938.

## GASTRO-ENTEROLOGY IN THE PRACTICE OF CARDIOLOGY

LOUIS FAUGERES BISHOP JR., M.D.

NEW YORK

The problems of gastro-enterology and cardiology in a given case are often closely related. Present day emphasis on the qualifications of a specialist increases the importance of retaining a broad outlook such as had the general practitioner of the old school. In the physician's efforts to become expert in a chosen field he must not become a localist. Most patients consult, or are referred to, the cardiologist with the belief that their condition is primarily due to a disorder of the heart, but many of their symptoms are of gastro-enterologic origin.

A study of symptoms reveals that the most frequent gastrointestinal symptoms encountered in the practice of cardiology are flatulence, anorexia, nausea, vomiting, dysphagia, jaundice and abdominal pain. It might be said that every patient with cardiac disease at some time or another complains of a gastrointestinal symptom. Confusion often arises in the interpretation of these symptoms.

A great deal has been written concerning the interrelationships of cardiology and gastro-enterology. The subject is still difficult to clarify. There is often discrepancy between clinical observation and experimental evidence. A better understanding of this problem can be had by a consideration of the cardiac-gastrointestinal relation under three main headings: (1) mechanical, (2) chemical, toxic and infectious and (3) reflex.

## MECHANICAL ASPECTS

*Cardiovascular Pathologic Conditions Affecting Abdominal Viscera*—Under the heading of mechanical influence of cardiac abnormalities on the abdominal viscera, among the most obvious are embolic manifestations from a valvular vegetation—mitral or aortic—or from a thrombus on the left side of the heart. For example, a young woman under observation for rheumatic cardiac disease apparently had an acute abdominal condition. Autopsy revealed an embolus in the superior mesenteric artery, with beginning gangrene of the segment of the intestine supplied by this vessel.

Failure of the right side of the heart with attendant venous congestion leads to chronic passive congestion of the abdominal viscera and thus interferes with the function of these organs. Among the common examples of gastrointestinal disturbance secondary to cardiac failure are hepatic distention with abdominal pain, a common picture in advanced mitral disease. Chronic passive congestion of the mucosa of the stomach sometimes results in nausea and vomiting, as well as a multitude of chronic digestive complaints. These are, on rare occasions, diagnostically confusing, particularly in patients receiving digitalis, but tend to clear up when cardiac compensation has been restored. In hypertensive cardiovascular disease with arteriosclerosis, hemorrhages, usually small, may occur in any of the abdominal organs, producing acute abdominal symptoms but having as a primary cause the underlying cardiovascular disease. Arteriosclerosis of the mesenteric vessels sometimes gives rise to symptoms of

abdominal pain, formerly called abdominal angina,<sup>1</sup> the exact functional pathology of which is not well understood.

In mitral stenosis of long standing the left auricle dilates, pressing on the esophagus, and occasionally gives rise to dysphagia. A recent example<sup>2</sup> of this condition occurred in a white American woman aged 33, who had as one of her complaints difficulty in swallowing liquids. On fluoroscopic examination a huge left auricle was found to be pressing on the esophagus. At autopsy the esophagus was seen to be compressed and pushed over to the right by the enlarged left auricle. It lay along the posterior aspect of the left auricle, looking something like a thin rubber tube stretched across the surface of an inflated balloon.

In similar fashion an aneurysm may disturb the position or function of the other organs by mechanical pressure, as on the trachea, esophagus and abdominal viscera, and thus cause symptoms related to the disturbed organ when the primary cause is cardiovascular. A recent example was observed in a white butcher aged 57, who had been under observation for coronary sclerosis and one day collapsed. On physical examination a tender mass was noted within the abdomen. This mass presented a difficult diagnostic problem. There was continuous pain in the left flank, with marked tenderness at the left costovertebral angle. During a gastrointestinal consultation to determine the nature and mode of treatment of the condition the patient died. Autopsy revealed a huge ruptured abdominal aneurysm.<sup>3</sup>

*Effect of Pathologic Conditions of the Abdomen on the Cardiovascular System*—Conversely, there are a number of intra-abdominal conditions which may have a direct mechanical influence on the function of the heart. Among the most frequently seen is flatulence. There is considerable discrepancy between clinical and experimental observation on the effect of flatulence on cardiac function. Clinically flatulence has been thought to be a potent factor in the production of extrasystoles, tachycardias and, in susceptible subjects, anginal attacks, by elevating the diaphragm and thus pushing the heart upward and disturbing its function.

In my experience unusually large amounts of gas have frequently been found in the stomach or colon on fluoroscopic examination, but this finding is rarely associated with any cardiac arrhythmia. Furthermore, Wayne and Graybiel<sup>4</sup> did not find any decrease in tolerance of exercise in persons with angina after the stomach had been distended with air.

The subject has been studied experimentally in dogs by Owen.<sup>5</sup> Electrocardiograms of lightly anesthetized animals were taken before, during and after dilation of the stomach with air. Changes in rate, usually a slight increase, and on rare occasions an extrasystole, were observed. Extrasystoles seemed to occur a trifle more frequently with belching than during distention. Of a number of medical students who could swallow air at

will and belch, none showed cardiac irregularities or significant changes in rate on electrocardiograms taken during the swallowing of air or belching.

The experiments in dilation of the stomach were repeated after attempts were made to render the heart susceptible by such means as feeding large doses of barium chloride, crushing one of the coronary arteries, inducing hyperthyroidism or diphtheritic myocarditis, using stimulants of the sympathetic and parasympathetic nerves or tying the common bile duct to produce jaundice. In the sensitized animals there was some increase in tendency to extrasystoles and to changes in rate after visceral dilation. The supposition is that the irregularities, when produced, were due rather to reflex stimulation, probably sympathetic judging from the work of Percy and Howard<sup>6</sup> than to mechanical distention of the stomach with pressure on the heart from elevation of the diaphragm. The effect then of flatulence on the susceptible human heart is questionable and, if affected, the mechanism is probably reflex rather than mechanical. From Owen's<sup>6</sup> studies of medical students the assumption is that flatulence and belching do not affect the cardiac function of nonsusceptible persons.

The same discrepancy between clinical experience and experimental evidence exists in the effect of abdominal distention from causes other than flatulence such as ascites, abdominal tumors and pregnancy, on cardiac function. From the clinical standpoint cardiac irregularities occurring in the presence of abdominal distention are thought to be due in certain instances to pressure on the diaphragm. But here again Owen<sup>6</sup> was unable to demonstrate the phenomena in dogs. He distended with air the peritoneal cavity of lightly barbitalized dogs and failed to observe any electrocardiographic changes before, during or after distention. Congenital defects in the diaphragm with diaphragmatic hernias belong to this group, but their effect on cardiac function is so individual and so related to the degree and character of the particular diaphragmatic anomaly as to make generalizations untenable. An example has recently been seen in a case of large diaphragmatic hernia with the stomach in the thorax anterior to the heart, in which there were no cardiac symptoms. The patient was entirely unaware of the anomaly.

#### CHEMICAL, TOXIC AND INFECTIOUS ASPECTS

*Cardiovascular Pathologic Conditions Affecting Abdominal Viscera*—The effect which circulatory failure with venous congestion and anoxemia may have on the electrolytes of the blood and tissue fluids is not clearly understood, but it is well known that in passive congestion and edema there is retention of salt in interstitial tissue, with resultant intracellular dehydration. Andrus and Carter<sup>7</sup> have shown that cardiac tissue is particularly sensitive to alterations in hydrogen ion concentration. This may occur in the cardiac muscle itself, through products of its own metabolism, or by changes in  $p_H$  or the carbon dioxide content of the fluid bathing it. Andrus and Carter suggested that the difference in hydrogen ion concentration within and without the cell is a factor in controlling its excitation. How sensitive are the tissues of the gastrointestinal

tract under these conditions? Long-standing chronic passive congestion of the liver may disturb its function so that a change takes place in the albumin-globulin ratio of the blood, the osmotic pressure of the plasma is lowered and the small globulin molecule has ready access to the interstitial fluids. By this means intercellular edema in the gastrointestinal tract and elsewhere is increased, and disturbances of gastrointestinal function result.

The fever, leukocytosis and high erythrocytic sedimentation rate following coronary thrombosis are evidences of generalized toxemia, with the cardiac lesion as the direct etiologic agent. Jaundice, which occasionally occurs in congestive heart failure,<sup>8</sup> may be a manifestation of toxemia or may again be only the result of hepatic congestion secondary to failure of the circulation.

*Effect of Pathologic Conditions of the Abdomen on the Cardiovascular System*—The number of extracardiac diseases which affect the cardiovascular system by some obscure chemical or toxic means is numerous. The field of gastroenterology certainly includes many of these—typhoid fever, acute and chronic dysentery and acute and chronic disease of the gallbladder, to mention only a few. The chemical mechanisms by which the cardiovascular system is affected in general toxemia from acute and febrile illness are not known. Myocardial damage has been demonstrated in dogs in acute diffuse peritonitis by Steinberg and Kobacker.<sup>9</sup> The study of the effect of accessory food substances on the heart and of the disorders of the gastrointestinal tract which prevent or delay absorption of these substances is still in its infancy but is an open, promising field.

#### REFLEX DISTURBANCES

*Cardiovascular Pathologic Conditions Affecting Abdominal Viscera*—The question of reflex disturbances which find their primary seat in the heart, with referred symptoms elsewhere, has received much attention, particularly in coronary thrombosis simulating acute abdominal disease. The mechanism of acute and chronic cardiac lesions giving rise to pain referred to the abdomen, simulating disease of the gallbladder, peptic ulcer and pancreatitis, is apparently the result of a crossed reflex arc whereby pain fibers from the cardiac regions enter a segment of the cord through the vagus or sympathetic chains and are confused with the impulses entering the same segment of the cord from the abdominal viscera, and thus the pain is "referred" to the abdomen. This referred pain is often seen in angina pectoris and pericarditis. This was strikingly illustrated not long ago in the case of a young married woman in whom an abdominal operation was contemplated for four days on account of prominent abdominal signs and symptoms. A pericardial friction rub, rapid enlargement of the heart and symptoms of progressive cardiac enlargement subsequently developed.

In abdominal conditions with cardiac manifestations the error of regarding acute disease of the gallbladder as coronary occlusion is all too frequently encountered. There is a good deal of real justification for this confusion. As mentioned before, there is the problem of referred pain, either from heart to abdomen or vice

versa, this is common in disease of the gallbladder. There is experimental evidence that under certain circumstances stimulation of the gallbladder may cause cardiac arrhythmias and produce changes in the electrocardiogram. Umber<sup>10</sup> reported tachycardia, irregularities and bradycardia as due to pain of the gallbladder. Hoppe-Seyler<sup>11</sup> described irregularities of pulse of vagal origin produced by gallstone colic. Straus and Hamburger<sup>12</sup> expressed the belief that extrasystoles in disease of the gallbladder may be due to stimulation of the vagus-supplied viscus (gallbladder), to absorption of toxin from the pathologic organ or to both. A series of experiments on dogs, begun by Owen<sup>5</sup> and continued by Crittenden and Ivy,<sup>13</sup> in which cardiac function was followed electrocardiographically after distention of the biliary system with air, did much to clarify the subject. As with distention of the stomach of normal lightly anesthetized dogs, Owen<sup>5</sup> failed to produce extrasystoles or irregularities other than slight changes in rate when he distended the gallbladder. It was found that jaundice, disease of the biliary tract or hepatic injury sensitized the animals to cardiac irregularities and even minor changes in electrocardiographic form. Crittenden and Ivy<sup>13</sup> confirmed Owen's<sup>5</sup> observations and further noted that the cardiac irregularities were due rather to the nausea and vomiting incident to biliary distention in the presence of jaundice than to the distention per se. They observed electrocardiographic abnormalities, such as extrasystoles and auriculoventricular blocks in 10 per cent of students who were nauseated and retched during the swallowing of a stomach tube. Carrying this work to observations on human beings during all kinds of abdominal operations, Maher, Crittenden and Shapiro<sup>14</sup> found suppression of the P wave and assumption of nodal rhythm in the majority and expressed the belief that the electrocardiographic changes are probably chiefly a result of deep anesthesia. Extrasystoles and bradycardia occurred in a few persons. The authors were unable to demonstrate any constant or specific relation between the particular surgical procedure and the cardiac response.

Bettman and Rubinfeld<sup>15</sup> attempted to eliminate the factor of anesthesia by using spinal anesthesia and limited the observations to operations on the gallbladder. They found that the effect of pressure, clamping and pulling on the gallbladder was to increase the cardiac rate. In a few cases extrasystoles developed during operation, one patient had shown them before operation.

Applying this work to clinical medicine, it is conceivable then to have electrocardiographic changes in the presence of acute disease of the gallbladder, particularly if jaundice is present, but these changes are probably related to nausea and retching and should therefore be transient. A heart which is itself sensitized because of pre-existing coronary sclerosis might, in the presence of disease of the biliary tract (which Owen<sup>5</sup> stated does sensitize the heart), show electrocardiographic abnormal-

ities on much less provocation than would a normal heart. In support of this hypothesis is the not too frequent observation, on which Straus and Hamburger<sup>12</sup> have reported, that patients with obvious coronary disease who in addition have chronic cholecystitis and cholelithiasis are sometimes rendered entirely free of cardiac symptoms, with return of the electrocardiogram to normal, after removal of the diseased gallbladder.

Further confusion in the differentiation between coronary and cholecystic disease arises from the fact that occasionally glyceryl trinitrate will relieve the pain in biliary colic by relaxing the cystic, or common duct, spasm, thus nullifying the efficacy of administering glyceryl trinitrate as a therapeutic diagnostic test in angina pectoris. On occasion it is almost impossible to differentiate the two conditions. A series of roentgen studies of the gallbladder, if the patient is in condition to weather it, may help to throw the weight of diagnostic evidence on one side or the other. This is particularly true if the studies give negative results, on the other hand, if they show a pathologic condition, with or without stones, one can never be sure whether in any one particular case this is coincidental or causative. If one recognizes the real difficulty in making the differentiation and remembers that cholecystic and coronary disease may attack the same type of person and therefore not infrequently coexist, one will steer an alert cautious course until the diagnosis is definitely established and thus avoid the error of operating on a patient with acute coronary thrombosis or progressive coronary sclerosis.

Other diseases which may be confused with coronary disease are gastric ulcers, acute pancreatitis, mesenteric embolism, acute intestinal obstruction, esophageal spasm and diverticulitis.

121 East Sixtieth Street

#### ABSTRACT OF DISCUSSION

DR. JOHN R. TWISS, New York. Pain is unquestionably an outstanding feature of both coronary disease and gallbladder disease. I have studied 200 patients with gallbladder disease from the point of view of pain. In no less than 50 per cent the pain was situated in the epigastrium rather than in the right upper quadrant, and in a large proportion of the patients the pain was referred to the precordium rather than to the back. Since glyceryl trinitrate may relieve gallbladder pain, a study of the associated symptoms is sometimes of assistance. I have found that the symptoms of indigestion with cardiac disease usually are associated with evidences of cardiac decompensation or to some extent following the taking of digitalis. The indigestion of the patient with disease of the gallbladder, on the other hand, is likely to be prolonged and intermittent, commonly following some dietary indiscretion such as overeating or taking foods to which the patient has an intolerance, such as fats. Being "afraid to eat" on account of the subsequent discomfort is a common story with cholecystitis. Further assistance in differential diagnosis may be obtained by physical examination in that conditions such as dyspnea, cyanosis and edema of the extremities are more common in the cardiac patient. With biliary tract disease I have found more frequently signs of localized tenderness and spasm of the right upper quadrant as well as jaundice. The laboratory tests which have proved most useful in establishing a diagnosis of biliary tract disease have been the cholecystogram, biliary tract drainage and the icterus index determinations. The existence in the same patient of both coronary disease and gallbladder disease, as stated by Dr. Bishop, is not uncommon. In my experience the most frequent sign in these cases is an appearance of extreme toxicity, usually associated with weakness and loss of weight. The blood pressure is commonly low, there may be cardiac irregularities, which I feel are due to a toxic myocarditis. Cholecystectomy has in

some of these cases given dramatic results not only in relieving the symptoms mentioned by Dr. Bishop but also in improving the general condition of the patient and eliminating attacks of pain which were apparently coronary in origin. In the absence of actual signs of decompensation, these patients usually stand operations well. Whenever possible a preliminary rest in bed is advisable, the glycogen reserve being built up by means of a high caloric, high carbohydrate diet.

## Clinical Notes, Suggestions and New Instruments

### DANGERS IN THE USE OF CHEMICAL HAIR STRAIGHTENER

FREDRIC LEWIS, M.D., NEW YORK

Consistent with the profession's eternal preoccupation with sordid materialism is the fact that there has been no literature on the subject of hair straighteners. A reasonably careful search, including perusal of the Surgeon General's Catalogue, the *Quarterly Cumulative Index Medicus* and *Chemical Abstracts*, demonstrates that, certainly for many years back, this phase of esthetics has been neglected. In some very incidental paragraphs it has been mentioned,<sup>1</sup> to be sure, that materials such as gum tragacanth might impose on the hair a brute force, gravitational kind of rectilinearity. But, while medical science slept, cosmeticians have pushed the borders of their own domain back far beyond this mucilaginous stage.

#### HISTORICAL

Chemical hair straighteners, according to the best available authorities, began to evolve toward 1910. Their origin is obscure, probably indeterminate. For a long time Negro women had been successfully straightening their tresses with a grease and hot comb mechanism, but for use on the closely cropped male pate there was needed a new invention. The tonsorial call was heard and from somewhere in New York was answered by an anonymous genius.<sup>2</sup> The industry has grown hardily, weathering intervening depressions and recessions as only a staple can, and today it sells its produce in Europe, Africa, South America and all over the United States. There are about six competing houses that distribute the straightener through drugstores and barber shops. Their clients—principally, but by no means exclusively, Negroes—are satisfied ones, and they write lavish, spontaneous testimonials in pencil.

The straighteners vary slightly in color and price and a great deal in strength, but fundamentally they are all of a chemistry. The 6 ounce jar (sufficient, perhaps, for three applications) costs somewhere between 40 and 80 cents. A busy drugstore may average two sales a day. The barber, charging a dollar a treatment, may have from one to five straightening contracts a month.

#### CHEMISTRY

The mode of action of hair straighteners is to make a supple out of a rigid shaft. The cystine moiety of the hair proteins can be broken at its disulfide bond to induce this fiber relaxation.<sup>3</sup> Thus the kinking, due to thickness gradations and axial twists,<sup>4</sup> may be overcome. Three general types of treatment can be responsible for this phenomenon:

- 1 Reducing substances, which ordinarily contain stannous chloride, sodium hyposulfite, sodium polysulfide and the like.<sup>5</sup>
- 2 Agents which bring large amounts of heat to the individual hairs by their exothermic reaction with water (calcium oxide, for example).<sup>6</sup>
- 3 Caustics, chiefly sodium and barium hydroxide.<sup>7</sup>

From Harlem Hospital

The chemical information involved was supplied by John V. Scudi, Ph.D., Department of Pathology, Harlem Hospital.

<sup>1</sup> In Queries and Minor Notes in *THE JOURNAL* and in Questions and Answers in *Hygeia*.

<sup>2</sup> Credit has been suggested for Asbury Park.

<sup>3</sup> Speakman, J. B., and Whewell, C. S. *J. Soc. Dyers & Colourists* 52: 380, 1936.

<sup>4</sup> Negro Hair Nature 132: 106 (July 15) 1933.

<sup>5</sup> Malone Carroll and McKee. U. S. 2,087,933. 'Composition for Straightening Curly Hair.'

<sup>6</sup> Rudolph List. U. S. 2,076,521.

<sup>7</sup> No references except as discussed in Speakman and Whewell.<sup>8</sup>

The reducing and the exothermic agents, followed by treatment to restore the original texture of the hair, are mechanisms prevalent in literature on the permanent wave. Hair straightening, on the other hand, seems to be effected exclusively by the caustic method. Three changes may occur under the influence of caustics: hydrolysis, imbibition and destruction of the disulfide linkage. The result is a malleable protein gel susceptible to mechanical straightening, a softer hair.

The commercial products surely differ as to all constituents but outstandingly in caustic content. The Federal Caustic Poison Act restricts the percentage of sodium hydroxide to 10, and so far as examination has shown the marketed straighteners are within this limit, although, obviously, there can be no regulation of their extralegal (?) manufacture in the home and barbershop. Much of the peril lies, no doubt, with such synthesizing amateurs who would do miracles of straightening.

The samples analyzed were whitish yellow creams, with a faintly disagreeable perfume, apparently in a petrolatum and soap vehicle. No evidence of a reducing or of an exothermic substance was found. Duplicate determinations on two different hair straighteners showed an average caustic content, titrated to congo red, of 6 per cent by weight.

#### REPORT OF CASES

CASE 1—J. D., a Negro youth aged 19, was seen in response to an ambulance call about 11 o'clock one night in December 1937. He was moaning in agony and daubing his cheeks with a wet cloth. The skin of his face was very edematous, covered with blotches of raw, red erosion, and diffusely erythematous—of an appearance identical with severe, second degree lye burns. The only relief from his excruciating "stinging" pain was continual moisture. An almost empty bottle of gray hair straightener lay on the table. The cream, unhappily, had been used on J. D.'s head, and the rinsings therefrom he had allowed to bathe his face.

Depigmentation from burn caused by hair straightener in case 2.

The patient was brought immediately to the accident room, treated with dilute acetic acid and analgesics and thence transferred to Bellevue Hospital. After three weeks he was discharged with the diagnosis of dermatitis venenata. Efforts to see J. D. for follow-up have been in vain, for he is gone with some fortuitous Harlem wind, nay, eddy, and his new address could not be found. It is probable, however, that the scars are permanent.

CASE 2—C. B., a Negro aged 45, was admitted to Harlem Hospital March 27, 1938, for pulmonary disease. A striking area of depigmentation on the forehead (as shown in the accompanying illustration) excited questioning, and a history of a burn from hair straightener was elicited. Seven years before, the patient's barber, while applying a cream for the purpose of straightening the patient's hair, got, as the patient relates, to talking of women people. Original sin haunted that barbershop and for fully five minutes enraptured its proprietor, though C. B. made efforts to tell him that something was burning his forehead. The sequelae are not accurately remembered by the patient, but apparently there were several days of soreness, then crust formation and gradual exfoliation with disappearance of chromatophores. The depigmentation proved enduring, but the straightening of the hair, alas, was transient.

DANGERS

The manner of use, as detailed by a large random sample of unimble barbers on Lenox Avenue, is in itself a confession of its dangerousness. The ears, the temples and all skin marginal to the hair is coated first with petrolatum. When the "tougher" of the products is used, a protecting layer of petrolatum is rubbed into the scalp itself. The cream is then smeared like icing on the dry hair and gently blended in. Thus it is left for a brief time—from one to twenty minutes, depending on the straightener's pugnance and the straightenee's sensorium. It must be washed off promptly with many rinsings of hot water and careful regard for the skin of the face. (Failing these precautions, 'it give your skin the devil'") Now the hair is straightened, it lies even as a hilly pool, and its texture is silken soft. The treatment is superbly effective. Relapses occur monthly.

It is difficult to estimate the extent of danger in the use of hair straightener. Certainly sensitivity to the caustic is widely variant among individuals. We ourselves made the serene sacrifice in the form of patch tests but suffered no ill consequence. Examination of the records of chemical burns of the scalp, face and neck admitted to Harlem Hospital in the last five years yields not a single one attributed to straighteners. Admitting physicians, on the other hand, have seen the inflammatory pathologic condition on many occasions and even patches of alopecia ascribed to straighteners. It is freely confessed by the barbers and the drugstore "docs" that bad burns may result from its imprudent use, but one must suffer to be beautiful.

SUMMARY

- 1 A reasonably thorough search of the literature reveals virtually no reference to hair straighteners as such.
- 2 Very persuasive hair straighteners are in general use. The cogent constituent is sodium hydroxide, which converts hair protein to a gel.
- 3 Their use is not without danger. Burns may be of such severity that the employment of straighteners is inadvisable except with great care or under the supervision of a qualified fireman.

DECOMPRESSION FOR EXOPHTHALMOS  
REPORT OF THREE CASES

FRANK B. KISTNER, M.D., PORTLAND, ORE.

In the remote past the profession was concerned over the distressing, often tragic, sequelae of progressive exophthalmos, particularly with those caused by hyperplastic goiter. With the development and progress of goiter surgery it seemed that the problem had been solved, but there remained a small percentage of patients with this condition who were not relieved, some even continuing a progressive course after surgical treatment of the goiter. I have also had an occasional idiopathic case.

Various procedures were suggested and carried out for the relief of these patients with little or no success until Naffziger and Jones<sup>1</sup> in 1932 reported the successful result of operation in six cases in the previous two years and established the principal etiologic factor in this condition. Naffziger's<sup>2</sup> article had a very complete bibliography on the subject of exophthalmos.

Swift<sup>3</sup> in 1934, entering the orbit by a modified Kroenlein approach for a supposed retrobulbar tumor, found that the unilateral exophthalmos was due to the same pathologic condition found by Naffziger, namely a tremendous enlargement of the extra-ocular muscles. His decompression was followed by complete relief of all symptoms. Space for expansion of the orbital tissues with Naffziger's operation is at the expense

of the tissues in the anterior fossa, the bulk of the bone removed being negligible. With Swift's procedure the result is due to the plasticity of the tissues in the temporal region.

In 1936 Sewall,<sup>4</sup> working on this problem in the laboratory, proposed utilizing the space occupied by the sinuses to gain room for the orbital contents. He states that he does not know of this method ever having been used for the relief of exophthalmos.

I am reporting three cases of decompression for exophthalmos, one by the Naffziger method and two as suggested by Sewall.

REPORT OF CASES

CASE 1—A man aged 22 was operated on in September 1927 by Dr. T. M. Joyce for toxic goiter. He had moderate exophthalmos, more pronounced in the right eye. Otherwise the eyes were normal except for a moderate refractive error. Following the operation there was little change in the condition of the eyes for seven or eight months, at which time it became apparent that the exophthalmos was becoming more pronounced.

Semidiagrammatic sketch showing incisions in the periorbital fascia, or periorbita after removal of the floor of the frontal sinus, the ethmoid cells and the lamina papyracea.

He was working and feeling fine in every other way. Physical examination revealed no other abnormality. He was given compound solution of iodine at intervals during the following five years, but the progress of the exophthalmos continued.

By June 1933 his eyes were so prominent that he could not wear his glasses. There was some limitation of movement, especially upward and on looking to the right. He had transient diplopia. The lids could be closed and there were no changes in the fundi. The right eye was much more prominent than the left and he said he could not see as well with the right eye as with the left. He insisted that something be done to relieve him.

June 15, Dr. Joyce and I operated on him according to Naffziger's method. The frontal sinuses were small. The ethmoid cells did not extend into the roof of the orbit. Bilateral frontal flaps were reflected, the dura of the frontal lobes was elevated, exposing the roof of the orbit. All the bony roof of the orbits external to the sinuses was removed back to and including the upper outer portion of the optic foramina. The

<sup>4</sup> Sewall, E. C., Operative Control of Progressive Exophthalmos, Arch. Otolaryng. 24, 621 (Nov.) 1936.

ligaments of Zinn were cut and anteroposterior incisions made in the fascia of the orbit. Postoperative recovery was uneventful. During the first few months following operation there was a noticeable regression of the exophthalmos, though the right eye still remained more prominent than the left. There was visible pulsation of the eye globes synchronous with the pulse.

It has now been over four years since the decompression. Neither eye has receded to its normal position. The right eye is 2 mm more prominent than the left. The patient complains of "jumps" in his eyes with each heart beat, which makes it very difficult for him to read. He states that the vision in the right eye is better than before the operation.

CASE 2—A married woman aged 30 presented herself at the Portland Clinic in July 1937 complaining of "bulging eyes." She gave the following history: Twelve years previously she had a sudden onset of swelling of the lids of both eyes. The swelling subsided, but the right eye continued to bulge and symptoms of toxic goiter developed. After three years she consulted Dr. W. B. Holden of Portland, who did a thyroidectomy. This relieved her toxic symptoms but not the exophthalmos. In August 1936 the left eye began to bulge and the vision to fail, but there were no symptoms of toxicity. In December more thyroid tissue was removed with no improvement of the exophthalmos.

Corneal ulceration had occurred many times—fifteen times in the right eye, according to her statement—and she had a continuous dead aching pain in both eyes which interfered seriously with her rest. She complained of an occasional diplopia. Vision in the right eye was 20/100, in the left 20/40. There was some fulness of the disk with nasal blurring and temporal pallor.

Aug. 3, 1937, I performed a bilateral transfrontal ethmoidectomy, removing the entire floor of the frontal sinus, the ethmoid labyrinth and the lamina papyracea back to the optic foramina. The bone at the foramen was not removed nor was the sphenoid entered. It is essential to remove or destroy the mucous membrane lining of the frontal sinus and supra-orbital ethmoid cells in order not to isolate secreting membrane in a situation that has inadequate or no drainage. The orbital fascia was opened by two anteroposterior incisions and one transverse incision. The anteroposterior incisions were placed one at the lower border of the resected lamina papyracea, the other at the upper border. The transverse cut was started at the external limit of the frontal sinus and carried internally across the anterior ends of the two previous incisions. Before closing, the mucoperiosteal flap was placed to protect the fronto-nasal opening.

Recovery from the operation was uneventful. The constant aching pain in the eyes was relieved in five or six days. It could be seen that the eyes were receding as soon as edema following the operation had subsided. The patient left Portland for her home twenty-three days after the operation. The eyes had receded 4 and 5 mm and she was comfortable. Reports from her since that time indicate continuous improvement in her vision.

CASE 3—September 25 I carried out the same procedure on a woman aged 26. Eighteen months before she had had a thyroidectomy for toxic goiter. There was some exophthalmos before the operation and it continued to progress after all the general symptoms were relieved. Various forms of treatment were tried without result. At the time of the transfrontal decompression there was some puffiness of the eyelids and lacrimation. She could not close her lids and had had a corneal ulcer on one eye. Mobility of the globes was impaired and her vision was failing. She left the hospital five days after the operation. At the end of the first week the lids could be closed. The eyes had receded to within normal limits in four weeks. The vision has improved and there has been some increase of mobility of the globes since then.

#### COMMENT

So far as I know this is the first report of the space occupied by the sinuses being utilized for the relief of exophthalmos.

The advantages of this operation over that of Swift or Naffziger are that it is less formidable, there is less disfigure-

ment from the scar than by the Kroenlein approach, it provides actual rather than potential space for expansion of the orbital contents, it does away with the pulsation of the eyes which was such a disagreeable sequel in the case in which I operated by the Naffziger method, and it can be done when widely extending supra-orbital cells would make the Naffziger procedure impracticable.

### THE PHARMACOPEIA AND THE PHYSICIAN

#### THE TREATMENT OF INFANTILE ECZEMA

FROM THE POINT OF VIEW OF THE DERMATOLOGIST

MARION B. SULZBERGER, M.D.

NEW YORK

*This is one of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee on Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed.*

According to modern interpretation, the term "eczema" describes not a disease entity but a more or less characteristic form of cutaneous reaction. Although it is difficult to give a brief, yet accurate, description of the eczematous reaction, I believe that the following definition enjoys the most universal acceptance. All "eczemas" consist of inflammatory reactions in the uppermost portions of the skin. These reactions are characterized, clinically, by one or more of the following: erythema, papulation, vesiculation, oozing, crusting, scaling and thickening, and, histologically, by intra-epidermal edema (spongiosis), vesicles, parakeratosis and acanthosis, and with concomitant, more or less marked, acute or chronic inflammatory changes in the upper cutis. This form of reaction is the most common of all dermatologic changes, "eczemas" of various types and from various causes rank with the common cold and with acne vulgaris as perhaps the most frequently encountered of all human diseases.

In recent years, dermatologists have been trying to distinguish more and more sharply between the various forms of eczematous and eczematoid dermatoses, as seen in older children, in adolescents and in adults. Most observers agree that in patients beyond infancy and in typical cases the expert should be able to differentiate between the following main representatives, each one constituting in all probability a more or less distinct entity, which is often fundamentally unrelated to the other forms:

1 Eczematous contact-type dermatitis (true "eczema" of Jadassohn,<sup>1</sup> Bloch<sup>2</sup> and many American authors)

This is the most common form of allergic cutaneous disease in adults, in all probability it is the most common of all allergic diseases.

2 Atopic dermatitis (Coca-Sulzberger) (synonymous with prurigo of Besnier, lichen chronicus disseminatus of Vidal,

This is the second of three articles on this subject.  
1 Jadassohn, Josef. *Dermatologie*. Vienna: Bern, Weidmann & Co. 1938. p. 41.  
2 Bloch, Bruno. The Role of Idiosyncrasy and Allergy in Dermatology. *Arch. Dermat. & Syph.* 19: 175 (Feb.) 1929.

"neurodermite diffuse" of Brocq and "spriet exudatives ekzematoid" of Rost)<sup>3</sup>

3 Seborrheic dermatitis or seborrheic eczema of Unna

4 Nummular eczema, "orbicular eczema," "parasitic eczema," the "exudative neurodermite" of Kreibich and the "true eczema" or "autosensitization eczema" of many English dermatologists

A common cutaneous disease of entirely unknown etiology and pathogenesis generally appearing in sharply circumscribed, round or oval plaques of various sizes, often highly pruritic and favoring the extensor surfaces

5 Eczematous and eczematoid responses to micro organisms, either present at the affected site or originating from foci elsewhere in the skin or elsewhere in the body (The latter are the eczematous microbids of Jadassohn, Drier and Bloch)

The best known representatives of this group are the eczematous fungous eruptions, known as dermatophytoses and dermatophytids, and the eczematous reactions to monilia

6 Eczematous and eczematoid eruptions from physical causes (friction, repeated trauma, scratching, light, heat, cold, moisture and the like) and from chemical irritation (alkalis, acids, salts, terpenes, and so on)

7 Lichen chronicus simplex circumscriptus of Vidal (circumscribed neurodermatitis)

8 Combinations of any and even of all the foregoing forms

It is undeniable that the great progress which has been made in the subdivision of these dermatoses in the age groups above infancy not only has led to theoretical advances and to an approach to clearer understanding of pathogenesis but has also been most fruitful in the practical management of many of these cases. Today the dermatologist usually approaches the problems of treating an eczematous or eczematoid eruption in an older child or in an adult by first attempting to subclassify the dermatosis in its proper category among the groups mentioned. For determination of the exact group or groups into which a particular case will fall often determines the entire therapeutic approach, the prognosis and the prophylactic measures. Methods that are successful in one group are often unsuccessful and even harmful in another.

For these reasons an attempt to classify, in a similar manner, the eczematous and eczematoid eruptions in infancy was obviously indicated (Here I define "infancy" as up to the age of 2 years)

One finds, most recently, that attempts to identify some of these various forms have gradually been advancing from the specialist into the pediatric and general literature both here and abroad. Hill<sup>4</sup> for example, who is the author of the most complete and recent practical chapter on this subject, is in essential agreement with the outlined classification,<sup>6</sup> he now distinguishes between infantile eruptions which may be classed as (1) seborrheic dermatitis, (2) eczematous fungous conditions, (3) contact dermatitis and (4) atopic dermatitis. But Hill too emphasizes the many combinations and transitional forms, the frequent insurmountable difficulties in differential diagnosis and the

fact that in infants the topical and dermatologic treatment is the same, or very similar, in all these different groups.

I should certainly be the last to deny the necessity for continued efforts in the endeavor to subclassify the eczematous and eczematoid eruptions in all age groups, for I have been a strong proponent of this endeavor and am convinced that examples of many or even all the forms found in adults may be present in infancy.<sup>5</sup>

However, the situation in infancy is distinctly different from that in adults, particularly because of the additional diagnostic difficulties encountered in infants. I doubt whether the nondermatologist who approaches the problem of practical treatment will, in the present rudimentary state of knowledge in this field, derive much of value in attempting to distinguish between the various forms of eczematous and eczematoid dermatitis in children below the age of 2 years. Some of the reasons for this doubt may be summarized as follows:

1 In infants the atopic form or forms in which atopy plays a major role is numerically so preponderant that each of the other types represents only a small, almost insignificant fraction of the total cases encountered (The criteria for establishing the atopic nature of infantile eruptions may be found in my previous papers<sup>6</sup> and in the other articles in this symposium.)

2 The localization in the infantile cases does not usually permit the clearcut distinctions often found in adults. In infants the scalp and face seem to be the sites of predilection not only in seborrheic but also in atopic forms, there is usually no marked favoring of antecubital and popliteal spaces, even in the most typically atopic cases. Thus the infantile eczematous eruptions do not, as a rule, present the typical distributions which constitute such important aids in the differential diagnosis of the adult forms.

3 The blistering and weeping, which are almost pathognomonic of adult contact-type dermatitis and which are absent in uncomplicated atopic and seborrheic dermatitis in adults, are likely to be present in all forms of infantile eczema.

In my opinion this may be merely a result of a difference in the properties of infantile skins which permit exudation from below to permeate and progress upward. The superficial structures then naturally respond with vesiculation (compare also the different type of whealing which cutaneous tests elicit in infantile, as contrasted with adult, skins). The superior tendency to vesiculation in young skins is seen not only in eczematous and eczematoid eruptions but also in the blisters encountered in many other infantile dermatoses, for in infants blisters often appear in dermatoses which are usually nonvesicular in adults (syphilis of pemphigoid type, bullous impetigo, bullous scabies, bullous reactions to insect bites, urticaria topped by small vesicles, miliaria and the like). In infants the vascular and urticarial reaction of atopic dermatitis<sup>7</sup> and the inflammatory edema of seborrheic dermatitis often lead to vesiculation, weeping and crusting, while these same cutaneous conditions produce no manifest vesicles or

crusting when older persons are affected. And thus, as previously mentioned, the most helpful clinical criterion in the attempt to distinguish between atopic or seborrheic and contact dermatitis in adults is likely to be entirely absent in the infantile eruptions.

4 In infants, the results of various forms of cutaneous tests and the changes with regard to antibodies do not help to differentiate between atopic and non-atopic forms in the same degree as in adults. For example, almost all patients with infantile eczema (over 80 per cent in my material<sup>8</sup>) have positive wheal reactions and reagins to egg-white, and, as Peck and Salomon<sup>9</sup> and Hill<sup>10</sup> have shown, also to cutaneous tests with house-dust and other inhalants and thus, by these criteria, would be atopic. However, many of these very cases would certainly seem to be strongly seborrheic, if one would judge only by the appearance by the clinical course and by the response to the therapy.<sup>8</sup>

5 The mixed forms, transitional and complicated cases (impetiginization, fungi and the like), exist in adults but are much more common in infants—so common, indeed, that many infantile cases cannot be further classified. The eruption in infants often presents a crusting, oozing, excoriated and superficially infected dermatitis of noncharacteristic and nondiagnostic appearance.

#### GENERAL MANAGEMENT AND THERAPY

When one considers these examples of the many difficulties which, in infancy, beset subclassification even by the expert and when one further realizes that, as stated, the vast majority of infantile eczemas are atopic and, more important still, that the management of all the different forms in infants is often identical, it seems to me that, from purely practical considerations and until medicine has acquired more accurate knowledge in this field, the nondermatologist will be more successful if he discards theory and, for the present at least, regards "infantile eczema" as a cutaneous eruption to be managed as a unit. The management of these cases is then reduced to questions of logical and dermatologic approaches, based on the characteristics and circumstances of the individual case, on the form and stage of the eruption and on the sites affected.

In other words the dermatologic treatment is determined by the state of the skin rather than by the cause or category of the eruption. In infantile eczema the most promising therapeutic approach is that which is directed against the presenting manifestations, for

example, the removal of crusts and scales, the combating of infections, the soothing of irritation, the alleviation of itching and the prevention of scratching regardless of the subclassification or technical name of the particular form.

In this approach it is well to remember, first, that one is often dealing with not one but at least two and sometimes even three or more patients. The mother and the other person or persons who are taking care of and are concerned with the child must be meticulously instructed in the proper procedures and must commonly be regarded as the major sufferers and reassured, calmed and inspired with confidence. To accomplish this, it is best to commence enumerating, for their benefit, the cheering points, approximately as follows:

1 The baby will almost certainly get over the cutaneous disorder. This is true, for, while about 50 per cent<sup>11</sup> of the adults with atopic dermatitis have had infantile eczema, only a smaller proportion of infantile eruptions go on to adult forms. In most instances there is spontaneous cure at about the age of 2 years or before.

2 No marks and no scars will be left by the eruption.<sup>12</sup> The child's skin has every prospect of eventually being as perfect as that of any other child.

3 The cutaneous condition is not contagious.

4 The baby is a "healthy" one. The inner organs, the blood, the nerves and so on are all in good condition. The general health, nutrition and the like of the baby will not suffer because of the eczema. (In spite of all the itching, the sleeplessness, the scratching and the often massive superficial infection it is remarkable to note that these children, almost without exception, maintain an excellent state of health, of nutrition and of rate of growth.)

5 Provided the local treatment is correctly executed, there is practically no danger whatever of "infection" or "blood poisoning" in spite of all the scratching. (Enlargement of the lymph nodes may occasionally be present but suppuration is rare.)

6 The baby is not really suffering to the extent to which it appears to be. When it gets over this trouble, no general impairment will remain and no memory of the episode. (Atopic babies are, of course, candidates for atopic cutaneous diseases and asthma and hay fever, but these later troubles cannot be regarded as actual sequelae of the infantile eczema.)

Reassuring statements of this type will often pave the way to cure by enabling the distressed family to compose itself and become of valuable assistance in the further management.

From this point on the treatment becomes purely dermatologic—with perhaps a dash of practical allergy. In our present state of knowledge—or, rather, of ignorance—the value of general pediatric or medical studies is surely negligible so far as finding systemic changes or other underlying disturbances as causes of infantile eczema.

The most practical point of view for both physician and mother, nurse or other attendant is that which regards infantile eczema as a result of maladjustment of the skin to the radical changes of environment which occurred when the baby moved from the uterus into the world.

8 As Schloss and his collaborators (Anderson A. F., Schloss O. M. and Myers Constance. The Intestinal Absorption of Antigenic Protein by Normal Infants. *Proc Soc Exper Biol & Med* 23: 180, 1925; DuBois, R. O., Schloss O. M. and Anderson A. F. The Development of Cutaneous Hypersensitivity Following the Intestinal Absorption of Antigenic Protein. *ibid* 23: 176, 1925; Lippard V. W., Schloss O. M. and Johnson Priscilla A. Immune Reactions Induced in Infants by Intestinal Absorption of Incompletely Digested Cow's Milk Protein. *Am J Dis Child* 51: 562 [March] 1936) have demonstrated in many infants there are likely to develop transiently not only precipitins but also positive specific wheal reactions to cutaneous tests after ingestion of a new article of diet. Most probably this will be found to hold true also after any massive exposure to a new inhalant or other environmental factor. It is therefore obvious that many of the evanescent cutaneous reactions to the foods that the infant has ingested or to the substances of his environment cannot be considered as signs of atopy; moreover many of these reactions including those to egg white are of course without clinical significance. Even the marked and persistent cutaneous reactions to egg white to house dust and the like which may perhaps be considered as a sign of atopy are surely not always a proof of the etiologic role of the specific substance. This was first clearly shown by Sallenbach (Untersuchungen über die Laktar und Storm Reaktion. *Arch f Dermat u Syph* 165: 198, 1932) in the case of egg white and infantile eczema (see Hill<sup>4</sup> Sulzberger Spain Sammis and Shanon<sup>6</sup> Peck and Salomon<sup>9</sup> and Hill<sup>10</sup>).

9 Peck S. M. and Salomon Gustav. Eczema in Infancy and Childhood I. Contacts as Etiologic Agents with Particular Reference to Feathers. *Am J Dis Child* 46: 1308 (Dec.) 1933.

10 Hill L. W. Sensitivity to House Dust and Goose Feathers in Infantile Eczema. *J Allergy* 9: 37 (Nov.) 1937.

11 Sulzberger M. B. and Goodman Joseph. The Relative Importance of Specific Skin Hypersensitivity in Adult Atopic Dermatitis. *J A M A* 106: 1000 (March 21) 1936.

12 This is true except in rare instances with exceptionally deep traumatization and infection.

The skin is not only the most delicate and the most exposed organ, it is also that organ which has, to the greatest degree, the function of protecting the individual from the outside world, of adapting the individual to the environment. It is therefore not surprising that certain skins—and apparently most particularly those of atopic babies—will suffer and will be unable at first to cope with the abrupt and radical transitions that take place in changing from intra-uterine to extra-uterine life. All the new substances of the outside world—dust, feathers, wool, silk, animal emanations, gases, vapors, cleansing agents, caustics (soaps!)—begin their onslaught, and the varying physical forces—heat, cold, light, moisture, friction, pressure—all must be met and compensated for by cutaneous adjustments and regulatory mechanisms. The hordes of living micro-organisms—fungi, bacilli, cocci and virus which begin to settle on the surface of the skin and take up their activities there—must be controlled and resisted. In addition to all these external attacks, the skin must learn to cope with the hematogenous supply of the products of diet and digestion and of substances absorbed by inhalation.<sup>13</sup> Moreover, the skin must be able to adapt itself to the products emanating from new foci of internal and external infection, to the products of metabolism and of cutaneous excretions and to the influences of the newly coursing nervous and other impulses.

It therefore follows that the eczematous baby should be protected, as far as possible, against the violence of these onslaughts. The temperature of the room and of the entire environment should be kept even (about 68 F). The clothing should be light, soft and cool, next to the skin smooth cotton or linen should always be used in preference to woolen or other rough materials.

The baby's skin should be kept clean and soft, and this must be accomplished without the use of soap. If there is one point on which all authors agree, it is this: Except on the scalp, soap is "poison" for most infantile eczemas. It is my opinion that the greatest care must be taken to see that no soap remains in the clothing or bed linen. The most thorough and repeated rinsing of all garments and linens is essential.

Instead of soap being used, the child should be sponged or bathed with tepid water to which bran, starch or oatmeal<sup>14</sup> has been added. In many cases it is advantageous to add tar to the bath. This can be done by putting from 2 to 3 cupfuls of solution of coal tar, N F, in the small tubful of water or by adding 1 or 2 tablespoonfuls of the purchasable oil of cade and sulfonated castor oil mixtures.<sup>15</sup> These baths may be given at intervals varying from twice a day to once every two or three days, according to the effects observed.

<sup>13</sup> Sulzberger M. B. and Vaughan W. T. Experiments in Silk Hypersensitivity and the Inhalation of Allergen in Atopic Dermatitis. *J. Allergy* 5: 554 (Sept.) 1934.

<sup>14</sup> Of course these additions must not be used in cases of allergy to the particular cereals. It is the first duty of the physician to guard against the error of prescribing any remedy which may contain an ingredient to which the patient is sensitive. In this connection it should be mentioned that proprietary remedies of unknown composition present unknown dangers and are therefore always improper therapeutic agents. Not only active therapeutic ingredients but also vehicles, bases and the like must be considered as possible irritants. It is not always easy to avoid the many pitfalls. But with due care the physician can usually avoid the obvious hazards such as those of prescribing ointments containing wool fat or wool fat derivatives in cases of sensitivity to wool or of recommending olive oil, peanut oil, sesame oil, corn oil, cottonseed oil, linseed oil or fish oil (vitamins) for topical or internal use in cases in which there is sensitivity to the respective cereals, foods, animals and the like.

<sup>15</sup> A mixture of this kind is manufactured by the Almay Pharmaceutical Company of New York.

Soap substitutes such as sulfonated oils or alcohols, aliphatic esters and other nonalkaline detergents may be given a trial.

In cases in which the bath does not seem to be well tolerated, baths must be discarded and other cleansing measures must be redoubled. These measures—and it should be noted that they are to be employed after every bath as well as in lieu of a bath—consist of

1 The careful removal of all crusts, scales and debris, often best accomplished after gentle sopping or after the application of wet compresses (see prescriptions 8 to 11 inclusive) or of bandages soaked in olive oil or liquid petrolatum (prescription 1 A and B).

#### PREScription 1—*Lubricating and Softening Oils and Greases*\*

A (Salicylic acid 1 to 2 per cent)  
Olive oil in sufficient quantity  
or

B Liquid petrolatum in sufficient quantity to make 120 Gm  
Label For softening and for removal of crusts. Apply as directed.

\* In all the prescriptions submitted with this article, medicaments that can be omitted or included in any number and at will are enclosed in parentheses. Square brackets are used to enclose medicaments which should not be used simultaneously but which may be used as substitutes for one another.

2 Theunction of the baby's entire skin with one of the oils mentioned, followed by a generous sprinkling of plain, unscented, finely powdered talc or zinc stearate or other mild dusting powder (for example the one given in prescription 2).

#### PREScription 2—*Mild Dusting Powder*

[Powdered Boric acid 1 to 3 per cent  
or

Tannic acid 1 to 3 per cent]  
Zinc oxide  
Zinc stearate  
Purified talc each in sufficient quantity to make 30 Gm

Mix and dispense in a sifter top can

Label Use freely as required

In the cleansing process, particular attention should be paid to the crevices and folds of skin—to the so-called intertriginous areas.

During the cleansing, the medicaments that have been applied should be removed gently with the oily or aqueous solution, care being taken not to injure the skin by rough measures or by too vigorous rubbing. It is better to leave some of the medicament and apply the new layer over the remains of the old than to use force in the process of removal.

Several useful oily or greasy prescriptions for removing medicaments and for lubricating the skin are here submitted (prescriptions 1 and 3).

#### PREScription 3—*Softening and Lubricant Cream and Soft Ointment Vehicle*

	Gm or Cc
Liquid petrolatum	30.0
White wax	7.5
Distilled water	12.0
Sodium borate	0.225

Mix and label. Apply by gentle massage and bandage on in a thick layer (if required).

(This preparation may be used also as a vehicle for antipruritics [menthol 0.25 per cent, phenol 0.25 per cent], crude tar from 5 to 10 per cent, naitalan (a distillate from Caucasian shale) from 5 to 20 per cent, ammoniated mercury from 2 to 5 per cent or almost any other topical medicaments except salicylic and other acids that will break down the emulsion.)

Among the other general hygienic measures, the care of the diapers deserves mention, particularly in intertriginous or gluteal eruptions. As already stated, these skins are almost always sensitive to friction and to alkalis and the diapers must therefore always be soft, clean, loose and free from every trace of soap. Rubber "panties" and the like should be dispensed with. More-

over, the effects of ammoniacal stool and urine must be obviated, this is most readily accomplished by rinsing the diapers with a mildly acid and antiseptic solution. In most cases it is sufficient to soak the napkins in a saturated solution of boric acid.<sup>16</sup> The affected intertriginous areas may be painted with a mildly antipruritic, parasitocidal and acidifying shake lotion, such as that given in prescription 4. In this prescription the resorcinol and the addition of solution of coal tar, N F, are particularly effective in cases of the seborrheic type and the resorcinol or the red mercuric sulfide alone in cases complicated by monilia and other fungi. When resorcinol is used on infants it is safest not to apply it to large areas. Signs of cutaneous irritation and particularly of systemic poisoning, i. e., phenoluria, must be watched for.

Among the other general measures, regulation of the diet, with the proper proportions of protein, fat and carbohydrates, as well as vitamins and minerals, should be carried out by pediatric methods according to the weight and general condition of the patient, the type of stool and the like. It is my experience, however, that such general regulation has little influence on an infantile eczema except in isolated cases and in infants who are obviously overfed and pasty. Of recent years diets such as those low in animal protein and high in fresh fruits and vegetables have been recommended in

*PRESCRIPTION 4—Mildly Parasitocidal, Soothing and Drying  
Antieczematous Paint (Shake Lotion)*

(Menthol)	0.25 to 0.5 per cent
(Phenol)	0.25 to 0.5 per cent
(Red mercuric sulfide)	1 to 2 per cent
(Resorcinol)	1 to 3 per cent
(Solution of Coal Tar N F)	1 to 5 per cent
Calamine lotion	sufficient quantity * to make 120 cc

Dispense in a wide mouthed bottle

Mix and label. Shake well and paint on affected parts three or four times a day using an ordinary flat varnish brush.

\* The calamine lotion N F contains 80 per cent of prepared calamine and zinc oxide.

atopic forms, and diets high in protein (casein) and low in fats and carbohydrates are said to be useful in seborrheic forms. The detailed discussion of dietetic approaches will doubtless be covered by Dr. Hill in the present symposium.

The elimination of possible allergens from the diet is of much greater importance than are general dietary measures. It is my conviction that the empirical approach is usually more fruitful than any other in children under 2 years of age. The approach through the history, the close observation of the effects of elimination and reexposure to certain foods and the constant awareness that a certain few foods are notorious offenders will prove to be more successful, as a rule, than reliance on the results of hundreds of cutaneous tests. For, although results of cutaneous tests are occasionally most useful guides, positive reactions to cutaneous tests are, in infantile eczema, often without clinical significance, even when accompanied by specific reagins, conversely, substances that fail to elicit cutaneous reactions may nevertheless sometimes be factors in the production of the eruption.

For these reasons certain almost obvious empirical conclusions are likely to be of greater help than any cutaneous tests. When an eczematous baby has a family history of asthma or hay fever and is being fed nothing but milk, the simplest and often the most effective procedure is to try the complete elimination

of ordinary milk and the substitution of denatured milk or a milk substitute.<sup>17</sup>

Moreover, if after a reasonable trial any case of infantile eczema has proved to be refractory to topical measures, it is advisable to undertake the elimination, one by one, of such potential common dietary causes as cow's milk, wheat, eggs, citrus fruits, spinach, peas, tomatoes, fish and fish products, named here in the approximate order of importance. The details of elimination, substitution and regulation of the diet to avoid deficiencies of any type are covered in the contributions of my colleagues in this symposium.

One of the most striking facts about infantile eczema, and one to which perhaps insufficient attention has been accorded, is the observation of the almost unbelievably potent effects of environment in the broadest sense of the word.

As has often been stressed, and as has recently been substantiated by Osborne, a high percentage of all infantile eczemas "clear up," sometimes with spectacular rapidity, on hospitalization or other radical change of environment and without any other therapy whatever.<sup>18</sup> This phenomenon is also observed in adult atopic dermatitis and in many other dermatoses.<sup>11</sup>

I am certain that Rappaport and Hecht will present convincing evidence to show that environmental allergens may be of great significance in certain cases of infantile eczema and that these allergens include particularly the specific house dust and the substances coming from pillows, mattresses, bedding, rugs, draperies and dyed and colored objects. It is therefore expedient to remove all sources of such dusts. No feathers,<sup>9</sup> kapok mattresses, overstuffed furniture, rugs or draperies should be present. The room should be as bare as barracks, with washable walls and floors, if possible. An iron cot with a sterilized horsehair mattress and plain, painted wooden chairs should constitute the bedroom furniture. If kapok and feathers cannot be removed, the mattress, pillows or other articles containing these allergens should be covered with so-called allergen-proof covers.

Whenever possible, these precautions should be taken as a routine not only because they sometimes result in striking improvement of the eczema but because some eczematous infants are surely strong candidates for future respiratory allergy, in which these environmental dusts may be of prime importance.<sup>19</sup>

In infantile eczema the face and scalp are the most common and usually the most important sites affected. Crusts should be removed from the scalp by soaking with the oil given in prescription 1. This oil should be applied two or more times a day by thorough massage and held in place with oil-soaked, soft linen or cotton

17 Rappaport B. Z. and Hecht, Rudolph. The Treatment of Infantile Eczema from the Point of View of the Allergist. J. A. M. A. to be published.

18 In controlled experiments I have been able to convince myself that the improvement in some of these cases was not due to dietary changes or to changes in the general care of the infant for the sudden improvement occurred even when the home diet was brought to the hospital and even when the mother continued in complete charge of the hospitalized child. The change responsible for the beneficial effects was therefore an environmental one in which the word "environment" may include a great many as yet unknown and perhaps purely physical factors.

19 I have often expressed the opinion that the environmental substances mentioned such as wool silk and dyed materials may produce vascular cutaneous reactions not only through inhalation or swallowing and subsequently hematogenous distribution to the blood vessels of the skin but also by direct exposure from without. I have previously referred to the permeability of the infant's skin as evidenced by the strong tendency to vesiculation. It is probable that this permeability exists not only to substances and fluids coming from within but also to those coming from without, so that allergens may penetrate transdermally and may thus produce atopic reactions even when the shock tissue is situated in the vessels of the cutis. This penetration may be possible even when the skin is undamaged and is of course almost certain whenever the skin is scratched and damaged and whenever the skin's protective continuity is interrupted.

cloth, covered with a bonnet or cap. Such a cap is easily made from the top of a woman's white stocking. After twenty-four, forty-eight or seventy-two hours of such treatment most of the crusts can usually be removed, and treatment with prescription 5, 6 or 7 may then be instituted. These ointments should be

#### PRESCRIPTION 5—Scalp Ointment 1

Solution of coal tar N F 5 per cent  
[Red mercuric sulfide 1 to 2 per cent  
or  
Ammoniated mercury 1 to 3 per cent\*]  
Combine with the soft ointment of prescription 3  
or in petrolatum sufficient to make 30 Gm

Mix and label. Rub gently into affected parts from two to four times daily and bandage as directed.

\* Effect must be carefully observed because of possible sensitization to mercury.

#### PRESCRIPTION 6—Scalp Ointment 2 Containing Sulfur and Salicylic Acid\*

Salicylic acid 2 to 3 per cent  
Precipitated sulfur 2 to 5 per cent  
Liquid petrolatum  
Wool fat  
Petrolatum each in sufficient quantity to make 30 Gm

Mix and label the same as prescription 5.

\* Do not use when mercury is used.

#### PRESCRIPTION 7—Scalp Face and Body Ointment

Solution of coal tar N F 5 to 20 per cent  
(Ammoniated mercury 1 to 3 per cent)  
[Combine with simple ointment U S P XI  
or

preferably without wool fat as in U S P XI to make 30 Gm

Mix and label. Apply and bandage as directed.

massaged in gently, twice a day or oftener, bandaged on a thick layer and removed gently with olive oil or liquid petrolatum before each new application. The scalp apparently tolerates soap and water as well as most other remedies to a much greater degree than does any other part of the body's surface, it is therefore permissible and often advisable to wash the scalp thoroughly with a bland soap before beginning treatment, and at intervals of once or twice a week thereafter.

#### PRESCRIPTION 8—Mild Astringent Solution

[Solution of aluminum subacetate N F or solution of aluminum acetate N F 240 cc]

Label. Dilute with from fifteen to twenty parts of water and use as a cleanser [or apply as a wet poultice or dressing].

#### PRESCRIPTION 9—Mild Astringent and Disinfectant Solutions

A Potassium permanganate (tablet) 0.065 Gm  
Thirty tablets

Mix and label. Add one tablet to approximately 1 or 2 pints of water (1:7,000 or 1:14,000 solution). Stir and dissolve thoroughly before using.

or

B Potassium permanganate 2.5 Gm  
Distilled water to make 120.0 cc

Mix and label. One half or one teaspoonful to 1 pint of water (approximately 1:12,000 or 1:6,000 solution of potassium permanganate).

#### PRESCRIPTION 10—Mild Antiseptic and Astringent Solution

Boric acid (crystals or, if crystals are not obtainable, powder) 120 Gm

Label. One teaspoonful to each tumblerful of hot water; allow to cool and apply as cleansing solution or as wet compresses.

#### PRESCRIPTION 11—Boro Salicylated Solution (Thiersch's Solution)\*

	Gm or Cc
Boric acid	12.0
Salicylic acid	2.0
Distilled water	1,000.0

Mix and label. Apply undiluted as a wet compress.

\* Pharmaceutical Recipe Book II, page 205.

In managing the facial eczema, the crusts and the more severely impetiginized and infected areas are first treated by repeated and assiduous sopping with absorbent cotton and oil (prescription 1 A or B with or without the salicylic acid, or with cotton moistened

with one of the mildly antiseptic and astringent solutions given in prescriptions 8, 9, 10 and 11).

Moreover, these solutions can be applied as wet compresses to great advantage, always provided the correct technique can be rigorously observed.<sup>20</sup> In the periods between these swabbings prescription 3 or 5 should be massaged in gently and reapplied as often as necessary to keep the face lubricated and constantly covered. All crusts that can be removed should be swabbed off with soft cloth soaked in oil (prescription 1) or with cream (prescription 3) at least twice a day.

After the worst of the crusting and impetiginization has been eliminated (usually in two or three days), the face is often best treated with crude coal tar (prescription 12 or 13).

#### PRESCRIPTION 12—Coal Tar\*

Coal tar N F 30 Gm

Mix and label. Paint on the affected areas and powder over with talcum.

\* May be used with or without masks and bandages. Not to be used on extensive infected or open areas.

#### PRESCRIPTION 13—Coal Tar Ointments and Pastes

A Coal tar N F 3 to 5 or even to 10 per cent [in zinc oxide ointment or paste of zinc oxide N F] in sufficient quantity to make 30 Gm

Mix

or

B Ointment of coal tar N F (this is 5 per cent coal tar in paste of zinc oxide) 30 Gm

Label. Apply to affected parts two or more times a day.

(This is the most universally employed and often the most effective of all topical remedies in infantile eczema. The possibility of local or general intolerance to coal tar must be borne in mind when this or prescription 12 is used.)

I have found direct application of undiluted tar, painted directly on the face—a thick layer covered with purified talc—to be one of the very best of all methods of treatment. This method of application has in my hands been not only more effective but also, on the whole, less likely to irritate than any other active remedy.<sup>21</sup> The tar should be left on from one to three days, and then a face mask with yellow or borated petrolatum should be applied for twenty-four hours. The tar painting should then be repeated, the layer to be left on for another two, three or four days, again followed by a day of lubrication. This procedure can be repeated several times more if necessary. (The baby should not be exposed to sunlight when tars in any form or other photosensitizing agents are used.)

Face masks should be made of soft, unstarched, smooth, closely woven linen or cotton cloth. The mask is cut with holes for the eyes and openings for the mouth and nose. It must be large enough to reach over the forehead to the occiput on top and to the middle of the neck below. It can first be tied by means of sewed-on tapes and then held in place with careful, meticulously adjusted windings of gauze bandage as shown in the accompanying illustration. Swartz and Reilly<sup>22</sup> give detailed and excellent directions.

If the mask is properly made and applied, it will often increase the efficacy of all the salves and ointments used, as well as help keep the tar in place. However, not every one is capable of making and applying such a mask, for these procedures require more experi-

20 Garbe William and Sulzberger M B. *Dermatology. Some Techniques of External Therapy*. Am J Nursing 36: 873 (Sept.) 1936.

21 There are very few cases of irritation from such applications of tar. Nevertheless it is safer first to try tar—as well as all other active remedies—on a small area only. Among the warning signs of the skin's intolerance to tar are increased itching, erythema, oozing and spread of eruption or pustulation and impetiginization and swollen lymph nodes. Such signs as well as any evidence of systemic toxicity call for immediate cessation of active treatment and return to indifferent remedies.

22 Swartz J H and Reilly M G. *Diagnosis and Treatment of Skin Diseases*. New York: Macmillan Company, 1935.

ence, skill, patience and care than does the usual surgical bandage or dressing. What has been said about face masks applies equally to all forms of dermatologic bandaging—for example, on the extremities. All dressings must be applied in the correct and orthodox manner and with the most precise exactitude, there must be no unevenness, binding or friction. In all dermatologic bandages, soft linen or cotton cloths—not gauze—must be used as the layer juxtaposed to the skin, which is to serve to hold the ointments or pastes in place. When properly applied, such bandages are decidedly helpful in many cases of eczema. When carelessly or incorrectly executed, both face masks and bandages are often worse than useless.

It is usually difficult, if not impossible, to treat the trunk or any large area with bandages and salves,

Face mask held in place with properly adjusted windings of gauze bandage

high concentrations of tar, phenol, resorcinol and the like should not be used on large surfaces because of the dangers of poisoning by absorption. The face and one or two isolated areas on the body are about all one should attempt to treat with the tar or with the

service than ointments. The lotions and liniments should be painted on thickly and evenly with a regular flat varnish brush three or four times a day. Only the excess of remaining lotion or liniment should be swabbed off, the new coat is to be applied over the lotion or liniment that adheres.

PRESCRIPTION 15—Soothing and Drying Lotion\*

Lecithinum to make 60 Cm

Mix and label. Apply to the affected areas twice a day.  
\*Most advantageous in subacute or slightly oozing eruptions. Useful alone or particularly with the incorporation of coal tar or one of the other tars listed in prescription 18. Any of the active agents mentioned in the ointment prescriptions may be incorporated here. May be applied with bandages or simply rubbed on in a thick layer, the surface powdered over liberally with plain talc and left without bandages.

dressings, provided it is rubbed and patted on smoothly and then covered with a thick layer of talcum powder, which is spread over and rubbed gently into the surface of the paste after the paste has been applied.

The methods here sketched and the few prescriptions here submitted do not, of course, pretend to be exhaustive. An infinite variety of other methods and of other combinations of medicaments can be and have been recommended. However, when all is said and done, it will be found that the medicaments which are recommended over and over again in all treatises on the topical therapy of infantile eczema consist, in the main, of coal tar, other tars, mercurials, resorcinol and sulfur—in manifold forms, permutations and combinations—and of these crude coal tar or one of its derivatives is the acknowledged best.

Rather than multiply and complicate his remedies and prescriptions, the physician should learn thoroughly the properties and actions of a few active agents and of a few vehicles—their indications, the manner of their

#### PREScription 20—*Sedative Mixtures*

Mix and label. One half teaspoonful in water three times a day (Bromodermas and/or other signs of intolerance should be watched for) or

B Phenobarbital 0.015  
Mix and make into a powder  
Label. One powder mixed well with milk formula three times a day if necessary

correct application and removal and their possible disadvantages. He must then be able to take the time and the trouble to teach those caring for the baby just exactly how the treatment should be executed, and in order to do this he must be in a position to explain each step in the minutest detail.

By beginning with simple and mild measures, by closely observing their effects, by changing to another measure only when lack of continued progress or when any by-effect or irritation makes the change necessary the physician will achieve satisfactory results in most cases. For it is often not what but how that makes the difference between success and failure in the treatment of infantile eczema.

The prevention of scratching, through tying of hands and feet to the bed, through splints on the arms, by means of metal cups on the hands or by the use of sedatives such as small doses of phenobarbital or combinations of chloral hydrate and bromides (prescription 20) all are permissible and even indicated in intractable pruritus. Although proper splinting and

tying may at first seem cruel, these measures are often the kindest in the long run. A sheet of cellophane perforated for the passage of the head and covering the pillow or mattress in back and the chest in front will sometimes prevent the disastrous results of the constant fretful rubbing of the face and head against the bedding. Sometimes daubing the face and scalp with hot solutions will stop an itch crisis. Care should be taken not to burn the part, the solution must be of a temperature at which the adult finger can be dipped and kept.

Other methods of controlling itching and other treatments of eczema in general have been suggested by numerous authors.<sup>1</sup>

Nevertheless a common sense selection of the foregoing dermatologic measures alone will prove useful in almost all cases and sufficient in many. For, in the "cure" of eczema in children below the age of 2 years, my experience has shown that the various factors can be ranged in the following order of importance:

1 Time. Most patients get well by the age of 2 years or before and many then remain free of cutaneous disorders.

2 Complete change of environment unfortunately this is possible only in rare instances.<sup>25</sup>

3 Meticulous execution of the application of topical remedies, and of the local management described.

4 In many cases in which removal from the general environment is out of the question, the elimination of a few notorious food allergens and environmental causes.

Through the advances made in classification and subclassification of forms of eczema, one may at some future time be able to dispense with many or all of the purely palliative and symptomatic measures which I have cited, for through increased knowledge of the pathogenesis and mechanisms of the various forms—through greater understanding of their basic causes, of their immunology and endocrinology and metabolism (vitamins?)—one will be able some day to discard many of the present approaches as obsolete and to apply more fundamental and causal therapy.

But for the present, and at the hands of physicians at large, correct local therapy, combined with common sense, patience, perseverance and proper instruction to those in charge of the treatment, promises the greatest success in the majority of all forms of infantile eczema.

25 Here hospitalization plays a most important role although many eruptions recur soon after return to the home. I am well aware that hospitalization of patients with infantile eczema is looked on with justifiable fear by most pediatricians in this country and in England because of the danger of contracting serious infectious diseases. However in many years and in a material of several hundred cases I have never seen a severe complication due to hospitalization. It is true that the patients with infantile eczema whom I have seen treated in hospitals have been exclusively dermatologic hospitals and wards removed from intimate exposure to infectious diseases. It seems to me that this may account for my happier experience. It is unfortunate that such segregation is so rarely possible in this country owing to the present lack of separate dermatologic institutes. During hospitalization or segregation proper precautions must of course be rigidly enforced. These should always include meticulous general care feeding and the avoidance of local irritation or infection or of poisoning by absorption of phenolic topical remedies applied to large areas.

## Special Clinical Article

### THE NEWER CONCEPTS OF INTESTINAL INFECTION

CLINICAL LECTURE AT SAN FRANCISCO SESSION

JOSEPH FELSEN, M.D.

NEW YORK

The present nebulous state of knowledge concerning intestinal infections is perhaps best illustrated by the obscure terminology of "diarrhea, enteritis and dysentery" used in public health reports all over the world. A peculiar admixture of pathology and symptomatology, it is a frank admission of our ignorance concerning their cause. To justify the presentation of this subject I undertook a worldwide survey covering the five year period from 1933 to 1937. This period was chosen so that the observations might be correlated with coincident investigations of bacillary dysentery. Comparative studies based on data furnished directly by public health officers and compiled from reports of the U. S. Public Health Service reveal the following facts:

1. As the reported cases of bacillary dysentery increase, the cases of unclassified "diarrhea, enteritis and dysentery" rapidly decline. The incidence of amebic dysentery remains low and approximately level.

2. There is a rising incidence of bacillary dysentery in the United States, the figures for 1937 being approximately sixteen times those for 1933. A similar trend is indicated in other parts of the world, notably Denmark, Scotland and England.

3. The general consensus regarding bacillary dysentery as well as unclassified intestinal infection appears to be that the former comprises the majority of cases and that the actual incidence of both is greatly underestimated. In many cases the disease is unrecognized or not reported.

4. Present indications are that bacillary dysentery already far exceeds typhoid as a public health problem in the United States and that the incidence will continue to mount until the rising tide forces vigorous and heroic measures for its control.

Since the problem of intestinal infection is largely that of bacillary dysentery, the first part of this paper will be devoted to its consideration. The second part will be concerned with the mechanism of nonspecific or unclassified infections, their underlying pathologic changes and clinical significance.

Bacillary dysentery may be defined as a systemic disease due to *Bacillus dysenteriae* in which both the enteric and the extra-enteric manifestations are caused by one or more toxins. This concept implies that the intestine is only one of several organs affected, an unorthodox observation which accounts for some of the new and atypical forms of the disease, which must be recognized before effective control can be instituted. They appear to represent adaptations to a new environment and virgin soil, for bacillary dysentery is no longer limited by geographic or seasonal boundaries. The meningitic type<sup>1</sup> is ushered in by typical meningitic

manifestations. Headache, drowsiness, stupor or convulsions may be present. The neck is held rigid. Kernig and Brudzinski signs may be elicited and some photophobia is evident. Spinal tap reveals a clear fluid under increased pressure, with normal cells and sugar, no globulin and negative culture. Within approximately twenty-four hours the enteric manifestation gradually increases until they dominate the clinical picture, the subsequent course being that typical of bacillary dysentery. In every instance there is a labial or nasal herpes, suggesting the possible association of virus with the neurotropic toxin. Instances of the meningitic form comprised 13 per cent of my cases in the Jersey City epidemic of 1934.

The pneumonic type<sup>2</sup> of bacillary dysentery starts rather abruptly with a chill, pain in the chest and short nonproductive cough. The patient feels "grippy," the cheeks are flushed and the temperature may rise to 106 F. On auscultation of the chest there are fine moist rales which persist after coughing. A roentgenogram taken at this stage reveals a localized area of increased density corresponding in location to the auscultatory signs. The clinical picture strongly suggests incipient lobar pneumonia. Within twenty-four to forty-eight hours, however, the pulmonary symptoms and signs subside to be replaced by the classic features of bacillary dysentery.

Chart 1—4. Incidence of diarrhea, enteritis and dysentery in the United States from 1933 to 1937. There were 79,042 cases with a yearly average of 15,808 and an average mortality for nine states of 17.8 per cent. B. Incidence of bacillary dysentery in the United States from 1933 to 1937. There were 56,102 cases with a yearly average of 11,220 and an average mortality for six states of 15.7 per cent. The figures are based on communications from state health officers.

The agranulocytoid type<sup>3</sup> is characterized by a blood picture closely resembling that seen with agranulocytosis. There is severe, progressive neutropenia with toxic changes and almost complete disappearance of the granulocytes. The intestinal signs and symptoms are prominent from the start and persist with unabated severity until the disease is terminated by perforation and death. Profound toxemia is a striking feature of this form of dysentery.

The appendicular form<sup>4</sup> of bacillary dysentery is of rather frequent occurrence and is characterized by manifestations in the right lower quadrant, mesenteric lymphadenitis and, usually, acute inflammation of the distal portion of the ileum. The abdominal pain and tenderness tend to shift with change in the position of the body. The leukocyte count may be normal or there may be actual leukopenia. The differential diagnosis between the appendicular form of bacillary dysentery and acute suppurative appendicitis is sometimes diffi-

Read in the Medical Division of the General Scientific Meetings at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 14, 1938.

The author wishes to acknowledge the many courtesies extended to him by health officers in the United States and other parts of the world in the compilation of figures on the incidence of bacillary dysentery and intestinal infections of unknown cause.

cult, particularly if the patient is seen early and diarrhea is not yet a prominent feature. In doubtful cases it is wise to operate but if the appendix appears normal to abstain from resecting it or the inflamed terminal portion of the ileum since persistent fecal fistula or peritonitis may follow.

During outbreaks I have encountered three other types of bacillary dysentery, asymptomatic, afebrile and constipated. The patients affected by these paradoxical forms of the disease are not healthy carriers. Clinical and laboratory examinations reveal the characteristic diagnostic criteria and the typical progressive stages of intestinal disease. It is this group of patients who are frequently responsible for the endemic perpetuation of the disease. The practical clinical inference is that all contacts should be examined daily for evidence of bacillary dysentery regardless of the presence or absence of symptoms. Sonne-Duval dysentery, which is rapidly increasing all over the world, is often described as being a relatively benign and asymptomatic disease. I have had, however, the distressing experience that some of my cases of severest involvement in recent years have been of the Sonne-Duval type. For this reason outbreaks, particularly among children, should be terminated promptly. There appears to be no appreciable placental transmission of agglutinins against B dysenteriae from mother to newborn infant,<sup>5</sup> suggesting the marked susceptibility of the latter to the disease.

There is a characteristic three stage pathologic change<sup>6</sup> in acute bacillary dysentery, affecting primarily the lymph nodules with secondary involvement of the mucosa or deeper structures. Stage 1 is that of punctate follicular hyperplasia, in which the enlarged follicles stand out like discrete grains of sand on a reddened background of inflamed mucosa. Within approximately twenty-four hours the centers of the follicles become necrotic, appearing on the mucosal surface like the mouths of tiny diverticula. This constitutes stage 2, or the stage of punctate follicular necrosis. The ulceration is progressive, so that the third stage, of discrete and confluent mucosa ulceration, reaches its maximum by about the fourth or fifth day. More than one stage may be seen in the same person, since reabsorption of toxin occurs throughout the course of the disease. Healing usually begins by the seventh to tenth day and is accompanied by rather obstinate constipation, which represents nature's effort at splinting the bowel to favor repair. Babies often die during stage 1 or 2, that is, within the first forty-eight hours of the disease, with toxemia, dehydration and acidosis. The major pathologic change is produced during this period, within which therapeutic serum proves most effective. The serums of greatest value are those of high antitoxin content, since the primary lesions are produced by the dysentery toxins. The dysentery toxins may be divided into the enteric and neurotropic, isolated by Olitsky and Kligler,<sup>7</sup> and the arthritic, myelotropic and pneumonic, which are hypothetical, the probability of their existence being suggested by clinical and laboratory evidence. The intestinal lesions are produced largely during the process of excretion of the absorbed toxin from the mesenteric blood vessels through the wall of the bowel into the lumen. This statement is based on the following obser-

ventions. 1 The intestinal lesions can be reproduced in the rabbit by the intravenous injection of the toxin. 2 An eighteen hour broth culture of B dysenteriae injected into the marginal ear vein of the rabbit under proper control conditions also causes the disease and the bacillus can be recovered within twenty-four hours in the intestinal canal. 3 Early lesions are often seen after B dysenteriae has disappeared from the intestinal tract. Diarrhea in bacillary dysentery is a purposeful attempt to eliminate the dysentery toxins. It ceases when this object has been accomplished, but its cessation is not synchronous with the disappearance of the intestinal ulcers. They gradually disappear during the postdiarrheal healing period of approximately ten days. From these statements it may be surmised that the practice by our forebears of administering castor oil at the onset of the disease has some scientific basis. It aims

*Incidence of Bacillary Dysentery, Amebic Dysentery and Unclassified Dysentery from 1933 to 1937, Based on U S Public Health Service Reports*

	1933	1934	1935	1936	1937

Grand total		81 114			

Note the steady rise in the number of cases of bacillary dysentery the incidence in 1937 being sixteen times that in 1933. Note the inverse relationship of bacillary to unclassified dysentery.

Chart 2—Relation of the incidences of bacillary dysentery, amebic dysentery and unclassified dysentery from 1933 to 1937. As reported cases of bacillary dysentery increase the incidence of unclassified dysentery falls. Note the steady low incidence of amebic dysentery unaffected by the fall in the curve for unclassified dysentery.

at eliminating the specific bacteria and their toxins before they are absorbed into the systemic circulation.

The essential diagnostic criteria in a typical case of acute bacillary dysentery may be summarized as follows.

1 Clinical. An incubation period, which may be as short as twelve hours, is followed by the sudden onset of abdominal cramps and diarrhea. Intestinal spasm and tenderness are always present, are most marked in the right and left lower quadrants, occur early and persist during the acute phase of the disease. They are due to involvement of the distal portion of the ileum and the sigmoid colon. Repeated sigmoidoscopic examination reveals the characteristic three stage pathologic change.

2 Laboratory. The diagnostic tetrad consists of a positive culture of material from the intestine early in the course of the disease, a rising agglutination titer, the presence of bacteriophage at a later period and the purulent character of the cytologic exudate.

7 Olitsky P K and Kligler I J. Toxins and Antitoxins of B dysenteriae Shiga J. *Exper Med* 31: 19 (Jan) 1920.

In concluding this brief consideration of bacillary dysentery I wish to mention the prophylactic value of mass vaccination, therapeutic serum and the use of blood from recovered patients. It is my opinion, based on clinical and experimental evidence that these are valuable preventive measures in sporadic and epidemic outbreaks. Vaccines to be effective must be made up of strains indigenous to the time and place.

The bizarre character of bacillary dysentery is not limited to the atypical acute forms. Follow-up studies indicate that approximately 10 per cent of the patients pass over into the chronic phase and have chronic ulcerative colitis or chronic distal ileitis. The increasing prevalence of these chronic infections, often passing under the guise of colitis or enteritis, appears to parallel the increasing incidence of bacillary dysentery. I have seen them develop from acute bacillary dysentery. One can readily surmise how difficult it often is to trace chronic "colitis" or "enteritis" to an initial bacillary dysentery infection, particularly when the acute disease dates back one or several years. In some cases the original diagnosis has been overlooked or the patient did not seek medical attention. Persistent study, however, will clearly reveal in many instances that the chronic infection merely represents a perpetuation of the acute phase of bacillary dysentery in which the lesions have never healed and secondary nonspecific infection has been superimposed. It is therefore advisable to follow up all cases of the acute disease for one year which represents the time necessary for the full development of the chronic lesions.

Besides the acute and chronic bacillary dysentery infections there is a second group, that of nonspecific intestinal infections. The latter form a heterogeneous class and are caused by a variety of bacteria, toxins and perhaps viruses. The mechanism of intestinal involvement is best understood by regarding the intestine as an organ which possesses a dual excretory mechanism. The first is the direct excretory mechanism, whereby substances which have been ingested are digested and the waste products eliminated directly from the body. It appears unlikely that the intestine, continually laved by a flora rich in pathogens or potential pathogens, can be affected solely by the direct action of ingested bacteria on its mucosal surface. The second, or indirect hematogenous, excretory mechanism implies that bacteria or toxins which have been absorbed into the systemic circulation from an enteric or extra-enteric focus are excreted in part through the intestinal wall into the lumen of the bowel and thus eliminated from the body. This applies not only to bacteria and their toxins but also to heavy metals, notably lead. The skin, kidneys and possibly lungs play a lesser part, the tetrad forming what may be termed the reciprocal excretory mechanism of the body, since these organs appear to form a mutually cooperative system. The great protective barrier of the bowel is its rich lymphoid deposits and reticulo-endothelial network. Each solitary acuminate lymph nodule and Peyer patch is embraced and penetrated by a delicate filamentous network of thin-walled mesenteric vessels. The earliest response to toxic agents in the blood stream is therefore seen in the lymphoid tissue, which undergoes rapid hyperplasia. In mild infections, punctate follicular hyperplasia may be all that is seen. In severe infections or intoxications there is marked congestion with necrosis and ulceration of the mucosa. Intestinal symptoms and signs may therefore be associated with any extra-enteric focus of infection. The result is a confusing clinical picture

because the intestinal manifestations predominate while the primary extra-enteric focus may appear unrelated or remain undiagnosed. I have noted intestinal manifestations with infections of the upper part of the respiratory tract such as the common cold, "grip" and streptococcal sore throat. In pharyngogenic hematogenous streptococcal peritonitis (so-called primary peritonitis) focal hemorrhagic necroses are produced, particularly in the distal part of the ileum. I have reproduced these lesions in healthy rabbits by the intravenous injection of eighteen hour broth cultures of the organisms recovered from human beings. The streptococci injected into the marginal ear veins of these rabbits under proper control conditions appeared in the feces within twenty-four hours.<sup>8</sup> In subacute bacterial endocarditis, multiple mucosal petechiae of the bowel are far more common than mesenteric thrombosis. Embolic intestinal lesions occur frequently with bacteremia due to the hemolytic streptococcus, *Staphylococcus aureus*, meningococcus or type 7 pneumococcus. In the case of pneumonia the most marked intestinal lymphoid response may occur with hyperemia, particularly when the pneumococcus is of type 7. Rheumatic intestinal necrosis is usually seen in or near the ileocecal region, simulates acute appendicitis and has as its basic pathologic condition pronounced rheumatic vascular changes. Acute necrotizing pancreatitis with transverse linear thromboses of the mesenteric vessels in the mucosa or submucosa is seen with periarteritis nodosa. In the case of typhoid it is noteworthy that positive fecal and urinary cultures are often obtained after the blood cultures become negative. This suggests that the blood stream rids itself of the organisms at least in part by eliminating them through the wall of the bowel into the lumen. The hematogenic theory of the portal of entry of *Bacillus typhosus* implies that the blood stream is invaded by penetration of the mucosa of the throat or intestinal tract. The enterogenic theory implies a direct passage of the organism through the intestinal mucosa with the production of local lesions in the lymphoid tissue followed by passive invasion of the lymph and blood streams. There appears to be no evidence, according to Goodpasture,<sup>9</sup> that *B. typhosus* actually multiplies within the intestinal canal.

While the possibility exists that in some of these diseases the organisms may be swallowed, survive the action of the acid gastric juice and intestinal flora and subsequently exert a direct action on the mucosa, the retrograde hematogenous route for bacteria or their toxins appears more plausible on the basis of experimental and clinical evidence. Just as in the case of the dysentery toxin, the absorbed toxic agent is excreted from the blood stream into the lumen of the bowel. In the process the intestinal wall may be irritated or injured and focal symptoms may ensue. Reabsorption of excreted toxin often occurs, and a vicious cycle may be established which lasts as long as the systemic infection persists. When this is the case, depending on the nature and severity of the infection, there is not always a responsive diarrhea. The judicious use of enemas or cathartics will therefore often relieve toxemia, particularly since the terminal part of the ileum and the colon appear to be the chief sites of the excretion of toxin. The indirect hematogenous excretory mechanism of the intestine is important in explaining many

<sup>8</sup> Felsen Joseph and Osofsky A. G. Pharyngogenic Hematogenous Streptococcal Peritonitis. Arch. Surg. **31**: 437 (Sept.) 1935.  
<sup>9</sup> Goodpasture E. W. Concerning the Pathogenesis of Typhoid Fever. Am. J. Path. **13**: 175 (March) 1937.

poorly understood nonspecific intestinal infections or so-called infectious diarrheas. The primary cause often exists outside the intestine, and search for specific noxious agents in the bowel is then futile. Focal intestinal symptoms often cease abruptly after the primary extraenteric focus of infection is eliminated, but they may persist for a longer period if necrosis and ulceration have been produced.

While it is apparent that steady progress has been made in our understanding of intestinal infections, much remains to be done. Cases numbering 79,042 of "diarrhea, enteritis and dysentery" occurred in twenty-one states during the five year period from 1933 to 1937, with a yearly average of 15,808 and an average mortality of 17.8 per cent for nine of the states. Improved and cheaper methods of transportation have introduced new factors in possible dissemination of disease, viz., the automobile, train, ocean liner and airplane. The situation presents a formidable public health problem requiring cooperative epidemiologic, clinical and research efforts for its solution. To this end an international dysentery registry has been established for the study of infectious diarrheas. It is hoped that by joint action there will ultimately be achieved a better understanding of this group of diseases with a corresponding diminution in morbidity and mortality, particularly among infants.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

**ANTI-ERYSIPELOID SERUM**—A serum containing the antibodies and antibacterial properties of *Erysipelothrix rhusiopathiae* (suis).

**Actions and Uses**—For treatment of the clinical condition known as erysiploid, which is not to be confused with erysipelas.

**Dosage**—It is suggested that from 10 to 20 cc be administered subcutaneously or intramuscularly and quantities of 0.25 to 0.5 cc at numerous places about the border of the lesion.

Jensen-Salsbery Laboratories, Inc., Kansas City, Mo.

**Anti Erysiploid Serum Jensen Salsbery**—Prepared from horses subjected to increasing subcutaneous injections of live cultures of *Erysipelothrix rhusiopathiae* (suis). The serum is derived from the blood of such horses by defibrination, centrifugation and Berkefeld filtration; it contains 0.5 per cent phenol as preservative. Technic used in preparation and tests for sterility of the product are in conformity with requirements of the National Institute of Health. Potency test on pigeons is employed in which 0.1 cc of the serum protects against infection lethal to controls in from three to four days. Marketed in vials containing 20 cc.

**DIPHTHERIA TOXIN FOR THE SCHICK TEST** (See New and Nonofficial Remedies, 1938, p. 435).

Parke, Davis & Co., Detroit

**Diphtheria Toxin Diluted for Schick Test**—Also marketed in packages of one vial containing 5 cc of diluted diphtheria toxin sufficient for fifty tests.

**IRON AND AMMONIUM CITRATES**—"Contains ferric citrate equivalent to not less than 16.5 per cent and not more than 18.5 per cent of Fe." U S P.

For standards see the U S Pharmacopeia under Ferric and Ammonium Citrates.

**Actions and Uses**—See general article Iron and Iron Compounds, N N R 1938, p. 279. Iron and ammonium citrates is a hematinic which is practically nonastringent.

**Dosage**—From 0.5 to 2 Gm.

**Capsules Iron and Ammonium Citrates 0.5 Gm (7½ grains)**  
Prepared by The Upjohn Co., Kalamazoo, Mich. No U S patent or trademark.

**CINCHOPHEN** (See New and Nonofficial Remedies, 1938, p. 177).

**CINCHOPHEN-MERCK**—A brand of cinchophen-N F.

Manufactured by Merck & Co., Rahway, N. J. No U S patent or trademark.

**DIGITALIS** (See New and Nonofficial Remedies, 1938, p. 186).

**Whole Leaf Tablets Digitalis Haskell 1½ grains** Each tablet contains one cat unit.

Prepared by Charles C. Haskell & Co., Inc., Richmond, Va.

**GREEN IRON AND AMMONIUM CITRATES** (See New and Nonofficial Remedies, 1938, p. 281).

The following dosage forms have been accepted.

**Ampoule Solution Iron and Ammonium Citrates Green 0.05 Gm (¾ grain) 1 cc** Each cubic centimeter contains green iron and ammonium citrates U S P 0.05 Gm and quinine and urea hydrochloride U S P 0.005 Gm in aqueous solution.

Prepared by The Upjohn Co., Kalamazoo, Mich. No U S patent or trademark.

**Ampoule Solution Iron and Ammonium Citrates Green 0.1 Gm (1½ grains) 1 cc** Each cubic centimeter contains green iron and ammonium citrates U S P 0.1 Gm and quinine and urea hydrochloride U S P 0.005 Gm in aqueous solution.

Prepared by The Upjohn Co., Kalamazoo, Mich. No U S patent or trademark.

**ABBOTT'S STANDARDIZED BREWER'S YEAST TABLETS**—Each tablet contains 0.5 Gm (7½ grains) of dehydrated brewers' yeast (*Saccharomyces cerevisiae*) and is biologically assayed to contain not less than 23 international units of vitamin B<sub>1</sub> and not less than 12 Sherman units of vitamin B (G).

**Actions and Uses**—For use in prevention and treatment of disorders arising from deficiencies of vitamin B<sub>1</sub> (thiamin chloride) and of vitamin G (riboflavin).

**Dosage**—Daily prophylactic dose against vitamin B<sub>1</sub> (thiamin chloride) deficiency, from three to six tablets, therapeutic dose, as prescribed by the physician.

Manufactured by Abbott Laboratories, North Chicago, Ill. No U S patent or trademark.

Abbott's standardized brewers' yeast tablets are prepared from a selected strain of *Saccharomyces cerevisiae* especially cultured. The yeast cells are washed and dried; the dry powder containing approximately 5 per cent of moisture and compressed into tablets.

The vitamin B<sub>1</sub> content of the tablets is determined by comparison with the international standard by the modified Smith rat curative method. The vitamin G content is determined by the Sherman-Bourquin method.

**AMINOPHYLLINE** (See New and Nonofficial Remedies, 1938, p. 503).

**Aminophylline-Gane**—A brand of aminophylline-N N R.

Manufactured by Gane Chemical Works, Inc., New York (Gane & Ingram, Inc., New York, distributor). No U S patent or trademark.

**Aminophylline-Searle** (See New and Nonofficial Remedies, 1938, p. 505).

The following additional dosage form has been accepted.

**Ampules Solution Aminophylline Searle 0.48 Gm 20 cc** Each ampule contains aminophylline Searle 0.48 Gm in sufficient distilled water to make 20 cc.

**CARBROMAL** (See New and Nonofficial Remedies, 1938, p. 155).

**Carbromal Tablets 5 grains**

Prepared by The Upjohn Company, Kalamazoo, Mich.

## REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH Secretary

### SULFAPYRIDINE

Recent reports from investigators indicate that a pyridine derivative of sulfanilamide [2(p-aminobenzene-sulfamido)pyridine or sulfanilamidopyridine] is apparently more promising in the treatment of certain types of pneumonia than sulfanilamide itself. A number of investigators, and manufacturers as well, requested the Council to coin a nonproprietary designation for this product. The Council has therefore adopted the term "sulfapyridine" (sulf-a-pyr-i-dine). The product is in an experimental stage and as far as present advices are concerned the government has not licensed it for interstate sale. The Council will publish a preliminary report on this product in the near future.

SATURDAY, JANUARY 7, 1939

THE ST LOUIS SESSION

Announcements at a recent meeting of the Council on Scientific Assembly of the American Medical Association with the secretaries of the various sections and with representatives of the Scientific Exhibit indicate that the annual session of the American Medical Association, which will be held in St. Louis, May 15-19 inclusive, will bring before the medical profession of this country many of the amazing developments in scientific medicine which have attracted attention during the year. Such topics as the new uses of sulfanilamide and its derivatives, the new work on the vitamins including the uses of nicotinic acid and vitamin K and the vitamin B complex, the progress made in the treatment of pneumonia, and recent investigations on the endocrine glands will be conspicuous features of the program.

In the Convention Number of THE JOURNAL, which will be published April 15, the preliminary program will be given in detail. Already, however, the secretaries of the sections have been overwhelmed with applications for places on the program, and many of the contributions that were offered have already been accepted. Several new features have been incorporated in the presentation of scientific material this year. Among them will be a panel discussion of pneumonia in infancy and childhood, in which the elucidation of scientific facts will be by discussion rather than by formal presentation of a manuscript. Several of the sections are planning combined meetings. For example, the pediatricians are combining with the otolaryngologists in a session on pneumonia, also the physiologists with the neurologists on the uses of sulfanilamide in conditions affecting the nervous system. The campaign on syphilis will have attention in a symposium in the Section on Dermatology and Syphilology. In the Section on Preventive and Industrial Medicine and Public Health there will be a symposium on air conditioning and respiratory diseases, and in the Section on Urology a special symposium on the use of new endocrine derivatives. Another special feature of the annual session will be joint meetings of several sections on the concluding day of the session.

Especially important as a part of the annual session of the American Medical Association is the close relationship between the Scientific Exhibit and the presentation of manuscripts in the scientific sections. For some years those who present new contributions in the various sections have had opportunity to exhibit the actual materials with which they worked, in the form of case records, microscopic slides, charts, diagrams and other material. The author of the manuscript is thus enabled to demonstrate at first hand to physicians who are especially interested the details of his work, forming for those who attend the session a magnificent postgraduate opportunity not available in any other way. The popularity of this feature is attested by the fact that many physicians spend almost their entire time during the week in the Scientific Exhibit. Every year there are an increased number of appeals that more time be given for attendance on the Scientific Exhibit.

The location of St. Louis at well nigh the geographic center of the United States, the magnificent railroad, airplane and other transportation facilities, the fine hotel accommodations with which excellent cooperation is becoming apparent, are indications that the St. Louis meeting will maintain the record of these annual assemblies as the high point of the medical year.

THE INDICTMENT OF THE AMERICAN  
MEDICAL ASSOCIATION

Last week THE JOURNAL published the complete text of the indictment of the American Medical Association and other defendants, in the District of Columbia, by a grand jury which, for some weeks, had heard a mass of evidence presented to it by attorneys from the Department of Justice. Elsewhere in this issue of THE JOURNAL appears a chronology of this case from the time when the so-called Group Health Association, Inc., first appeared on the scene in the District of Columbia to the time when the grand jury made its report. Also in the Organization Section will be found a number of editorials and cartoons which have appeared in newspapers throughout the United States indicating, as far as such pronouncements can indicate, the public reaction to this extraordinary indictment.

At the special session of the House of Delegates which was held in Chicago in September, the Board of Trustees of the American Medical Association, anticipating the government's activities, presented a consideration of the possibility of an indictment. This matter was referred by the House of Delegates, as is customary, to a reference committee and the report of the reference committee was unanimously adopted by the House of Delegates. This report authorized the Board of Trustees to employ suitable legal counsel and to carry this matter even to courts of last resort in order to determine the issue.

Apparently the press of the United States finds it impossible to separate the activities of the Department of Justice from the proposal of a vast expansion of

medical service under governmental control. Thus Gerald G. Gross, in the *Washington Post* of December 25, writes "A convincing case can be built up to support the theory that the extraordinary grand jury study was, to put it bluntly, propaganda looking forward to Congressional consideration of the proposed National Health Program."

The commentators in the American press, including even those newspapers which have been most persistent in the campaign for new methods of medical practice, have been well nigh unanimous in their opinions that the action of the Department of Justice under Mr. Thurman Arnold was the wrong way to achieve the objective if that objective is to be achieved. Certainly this legal procedure can do nothing to solve the problem of medical care. It is a pity that the federal government, including its executive, investigative and a considerable number of other departments, should have embarked on a procedure which is inclined to cast public discredit on a great profession and to impugn the motives of workers in that profession. Moreover, a suitable defense will cost the Association a considerable sum of money that in the ordinary course of events would have been spent for the advancement of the science and art of medicine and the protection and promotion of public health. The time may yet come when those representatives of our government who have been chiefly responsible for initiating, conducting and manipulating this performance with all of its far-flung manifestations will review regretfully the part they have played in this incident.

### INDUSTRIAL CARBON DISULFIDE POISONING

The making of artificial silk, rayon, by the viscose process is an important industry in all industrial countries. In the United States this industry, which has grown rapidly during the last thirty years, employs now more than 50,000 persons in some twenty factories in thirteen states. This industry utilizes one poison, carbon disulfide ( $\text{CS}_2$ ), another, hydrogen sulfide ( $\text{H}_2\text{S}$ ), is evolved during certain processes. The presence of these hazards brings viscose manufacture into the class of the dangerous trades in most countries, notably Germany, France, Italy, England, the Netherlands and Japan. Especially in the first three of these countries, much attention has been drawn to the action of carbon disulfide. This poison, according to Koester,<sup>1</sup> produces as varied a clinical picture as does lead.

In the United States a period of thirty-three years elapsed between the publication of an article on this subject by Jump and Cruice<sup>2</sup> in 1905 and one by Gordy and Trumper<sup>3</sup> in 1938. Not only was the industry

expanding rapidly during those years, however, but the foreign literature was full of case histories of carbon disulfide psychosis, neuritis, paralysis and peptic ulcer. American physicians, even those in charge of institutions for the mentally disturbed, which draw patients from viscose factory towns, have never recognized carbon disulfide poisoning as a clinical entity. Until recently systematic investigation had never been made of this trade. Now the Pennsylvania Department of Labor and Industry has issued a bulletin on the manufacture of rayon in that state. This report contains a medical section by specialists from the University of Pennsylvania School of Medicine who examined 120 men employed at the time in the two departments in which carbon disulfide is present in greatest quantity.

The Pennsylvania group was under the leadership of F. H. Lewy, formerly head of the neurologic institute of the University of Berlin, now on the faculty of the University of Pennsylvania, who had made a study of the rayon industry in Germany. The object was not so much to uncover cases of severe poisoning, unlikely to be present in a working group, as to observe the early symptoms and signs and to develop, if possible, new diagnostic procedures for the guidance of industrial physicians. Stress was laid on the application of apparatus and methods giving quantitative results: for instance, the testing of the pupillary reflex to light with the Zeiss pupilloscope, sensitivity with von Frey's graduated hairs and thorns, the electrical irritability by chronometry, the size of the blind spot with the help of the Peter campimeter, defects of the central fields with the Lloyd stereocampimeter and the Hartz scotometer, the acuity of hearing with a Western Electric 2A audiometer in a frequency ranging between 32 and 13,000, and the heart with the portable electrocardiograph.

Carbon disulfide poisoning became known to the medical world through the classic description of Delpech,<sup>4</sup> who observed rubber workers<sup>5</sup> in France and in 1856 published his first report on the mental and emotional changes caused by this poison. The first German article to attract attention was Laudenheimer's<sup>6</sup> monograph in 1899 describing some fifty cases of carbon disulfide psychosis observed in Flechsig's clinic in Leipzig. Italy's contributions came later, but in recent years Italian investigators have led the world in the study of this occupational poison.<sup>7</sup> The noxious effect of carbon disulfide on the nervous system is attributed to its fat-solvent properties, but it is far more toxic than many good solvents such as the higher alcohols,

4 Delpech A. L. D. Accidents produits par l'inhalation du soufre de carbone. *Gaz hebdomad* 1856 p. 384.

5 Carbon disulfide was used in the so-called Parkes process for curing rubber known in this country as the acid or cold cure. This has largely given way everywhere to the heat cure and is no longer used in the United States.

certain of the chlorinated hydrocarbons, ether or acetone. The commonly observed early symptoms are insomnia, fatigue, listlessness and loss of initiative, depression of spirits, irritability and causeless anger, loss of memory and premature loss of libido. Later on paralyses develop, impairment of vision or temporary blindness, headaches, perhaps acute hallucinatory psychoses, impotence, emaciation and cachexia.

The 120 men examined in the Pennsylvania study exhibited these symptoms in their early stages but unmistakably, thus furnishing confirmation of the European work done in this field. To summarize briefly the results, 71 per cent showed psychic disturbances varying in degree from severe insomnia with bad dreams to extreme irritability, uncontrollable anger with rapid changes of mood, marked memory defects and in some instances psychoses, usually of maniacal type. Loss of libido was found in 75 per cent of the men under 45 years of age. The nerves most commonly involved were the peroneal and the radial and ulnar. Seventy-five per cent of the men suffered pain or, less often, decreased sensitivity in the early course of the intoxication, followed by weakness and partial paralysis. Determination of chronaxia proved valuable in the quantitative evaluation of early changes in motility. A decrease of corneal and pupillary reflexes was observed in half of those examined. Parkinsonism of various degrees occurred in 16.5 per cent, i. e. in every sixth or seventh man. The influence of carbon disulfide is seen in the fact that a third of those afflicted with parkinsonism worked in the churn room, the place of greatest exposure to carbon disulfide, while these workers represent only one thirtieth of the whole number exposed to carbon disulfide. In addition, three were found with the typical thalamic syndrome, in one case combined with parkinsonism, in another with choreoathetotic movements. Fifty-four per cent showed some ocular disturbance, such as enlargement of the blind spots, contraction of the peripheral fields, anesthesia of the cornea (partly due to the effect of hydrogen and sulfide), diminution of the pupillary reflex and nystagmus. This enlargement of the blind spot has not been previously reported in medical literature, and the diminution of the pupillary reflex has been mentioned only rarely. In the ear, the cochlear and vestibular nerves were involved in 71 per cent of those examined. The most important change found was a lacuna in the hearing curve, like that accompanying tobacco-alcohol amblyopia, which was found at the frequency of 4,096 double vibrations. This hearing loss, which is above the range of speech frequency, was detected in more than half of the men. Examination of the blood showed, as the most consistent abnormality, an alteration in morphology and staining properties of the monocytes, which exhibited a slaty blue cytoplasm crowded with minute neutrophilic granules and numerous vacuoles. Such "toxic monocytes" were found in almost every

specimen examined and constituted about 90 per cent of the monocytes counted in each case. It is noted that only 5 per cent of the specimens of blood examined gave a positive Wassermann reaction, a low proportion for an industrial group, according to the figures of the U. S. Public Health Service.

An important contribution to the literature of carbon disulfide poisoning is the report of a necropsy on a viscose worker, a spinner for twenty-two years, who died after an operation on the gallbladder. Extensive parenchymatous degeneration of peripheral nerves (sciatic and intercostal) was found and toxic changes in the ganglion cells of the cerebral cortex. The pathologic changes in the liver, kidneys and heart muscle were possibly to be attributed to the cholecystitis. This is a valuable addition to the scanty number (four in all<sup>3</sup>) of necropsy records published up to now.

## Current Comment

### VENEZUELAN EQUINE ENCEPHALOMYELITIS

Coincident with the recent severe epidemics of equine encephalomyelitis in Canada and the United States, a similar disease was recognized in Venezuela. Portions of the brains of horses dying of this disease were sent to Beck and Wyckoff<sup>1</sup> of the Lederle Laboratories for comparison with the northern types. When inoculated into guinea pigs and mice the Venezuelan virus produced symptoms similar to those of eastern encephalomyelitis. The virus, however, was from ten to a hundred times more virulent (or in greater concentration) than the usual eastern strain. Vaccines made from the Venezuelan strain and treated with formaldehyde would confer a solid immunity against the Venezuelan type. Cross protection tests, however, showed that solid immunity against the western virus was not accompanied by a demonstrable increase in resistance against the Venezuelan strain. Eastern immune guinea pigs also could be infected with the South American strain. A solid immunity against the Venezuelan virus, however, protected against a single minimal lethal dose of the eastern virus but showed no demonstrable protection if tests were made with ten or more minimal lethal doses of eastern virus. The results of the cross protection tests demonstrate that the Venezuelan virus is immunologically distinct from the western North American type of this disease but presumably has a minor heterophile factor common with the eastern virus. For all practical purposes, therefore, three immunologically distinct epidemics of horse encephalomyelitis must now be recognized on the Western Hemisphere. A polyvalent vaccine containing all three types of the formaldehyde treated virus is now the subject of experimentation.

## PRESS COMMENT ON THE INDICTMENT

### A PREPOSTEROUS INDICTMENT

[St. Louis Daily Globe Democrat Dec 21 1938]

The indictment by a federal grand jury at Washington of the American Medical Association, three local medical societies and twenty one individual physicians indicates the lengths to which Assistant Attorney General Thurman Arnold is prepared to go in waging war on what he chooses to term monopolies. As a matter of course, when Congress years ago passed the antitrust laws it never dreamed that they would or could be applied to such conditions as Mr. Arnold is now attacking. Indeed, there is no reasonable basis either in the spirit or the letter of these laws for such official procedure by the Federal Government. Mr. Arnold is simply making his own laws and by means of criminal indictments on charges that in no proper sense can be regarded as criminal is endeavoring to force organizations which for any reason he does not like to consent to regulations of his own that Congress has never authorized. The "consent degree" which by such coercive procedure he forced upon the automobile companies, applying to their relations with automobile credit associations, is the most recent instance.

Mr. Arnold is presumably in favor of "Socialized Medicine," and because the American Medical Association—which is said to include in its membership 110,000 of the 145,000 physicians practicing their profession in this country—is actively opposed to the forms of socialized medicine recently developing here, he subjects the Association, and many of its members individually, to criminal indictments. The American Medical Association contends that the group health associations against which it has taken its stand tend to lower the high standards of medical practice and to break down the close relations between the physician and his patient. There are certain attractions in the idea of group health insurance which appeal to large numbers of people, but whether it is really in the public interest is a debatable question. Certainly the great majority of physicians do not think so.

And because they do not think so they are, through their vast organization, subjected to criminal indictment by what is erroneously called the "Department of Justice." Regardless of the merits of the controversy no more tyrannical procedure by government could be imagined than this in a country that is still supposed to be free. It is a threat to every organization of citizens, professional or otherwise, that is established for the promotion of common interests. If one can be subjected to such pressure others can be whenever charges against them can be trumped up by an official of the Department of Justice disposed to take such action. The American Bar Association itself could be made answerable to criminal indictments if the Department of Justice as now conducted saw fit to charge it with conduct displeasing to Mr. Arnold. While Congress is investigating this, that and the other it had better look into the conduct of the Department of Justice, else, who knows, it may also be indicted.

### MISUSE OF A LAW

[Herald Dispatch Huntington W. Va. Dec 21 1938]

Application of the Sherman antitrust law to the professions is an idea that only the New Deal could have been expected to conceive. The launching of a criminal prosecution against the American Medical Association is on a brazenness par with the attempt to pack the supreme court of the United States.

Laws, especially federal laws, are peculiar. Often they are so worded that their actual purport can be stretched to points entirely beyond the intent of their framers and this may prove true in relation to the charges brought against the A. M. A. and certain individual physicians. But it is patent that the congress which enacted a law for the curbing of industrial and commercial monopolies never dreamed that it might some day be used for the harassing of the professions.

The word "professions" is used advisedly, for if it can be applied to physicians it certainly can with equal force be directed to dentists, lawyers, engineers and any other organized professional group—even ministers and churches.

So far fetched is the Sherman law prosecution of the "medical trust" that it can only be construed as being based on a vengeance motive, vengeance because the A. M. A. has been cool toward the administration's medical care program.

News of this prosecution will stir the nation profoundly. Whatever the result of the proceedings in the courts themselves, they will serve to widen, not heal, the breach between the government and the medical profession as well as to center the attention of the public on the subject of medical, surgical and hospital costs.

News of the action of the department of justice followed almost immediately upon that of a pioneer step in socialized medicine taken by the California Medical Association. This association has approved a health insurance plan with medical, surgical and hospital care on a basis of about \$2.50 a month.

This insurance is to be sold only to wage earners whose maximum incomes do not exceed \$2,500 annually.

Under it, the patient is to choose his own physician and hospital. Physicians are to be paid on a unit basis, with no interference with private practice.

The California experiment will be watched attentively by the nation at large. Wherever it exists it is on an experimental basis, working toward the solution of the widely recognized problem of medical care and toward the averting of the socialization of medicine in an actual sense by the assertion of government or state control.

### ABOUT DOCTORS

[New York Daily Mirror Dec 22 1938]

Most of the idealism, the self sacrifice, the unselfishness, the burning passionate interest in the welfare of humans, the unflinching devotion to their duty, and the deepest religious convictions that exist in the young men who begin their lives in America, you will find in those young men who enter medical schools.

As doctors, these young men have gone on to raise the standards of American medicine higher than you will find in any of those European or Latin American countries that boast of their "socialized medicine."

The average American receives medical care that is better than the best that the rich or the politically powerful can get from their specialists in Europe.

The problems of the American medical profession, and its standards, are matters which we as a newspaperman cannot hope fully to understand, would not dare try to dictate. We have not had the training of a Man of Medicine.

By the same token, we do not believe that any brush-lipped college professor—who was chiefly noted at Yale for his campus-variety wit and his delight in the sound of his own voice—we do not believe that such a man as Thurman Arnold is remotely qualified to set up through coercion a code of "fair practice" for those skilled men who devote their lives to healing the sick.

We believe that Thurman Arnold has unwittingly raised an issue that lawyer-politicians would prefer to keep quiet.

How much more of our freedom of action, of our liberties to engage in the exchange of goods and services, must we sacrifice to the obsessions of legalistic department dictators in Washington who have unlimited power to regulate a productive system which they do not understand?

Such a dictator is this Thurman Arnold, who has used his power to indict as a tyrant's club to force the American Medical Association to alter a position taken by the democratic action of its members.

He cracks down on the Medical Association and presumes to say that it has "restrained trade" by disciplining its own members and controlling the growth of "group medicine."

Mr Arnold refuses to recognize that there are already 2,000 such cooperative medical groups operating in America, with the full approval of the Medical Association, because they do not RESTRAIN the patient's right to choose his own physician.

Mr Arnold refuses to recognize the very danger which he best represents—the POLITICAL control of the medical profession.

Woodrow Wilson once said "Every man who takes office in Washington, either grows or swells."

Mr Arnold is "swelling." Tomorrow, we'll tell you how he uses his "consent decrees" as a club to enforce his 'benevolent despotism'."

## The Tyrant

Thurman Arnold, ex college professor and now trust busting Assistant Attorney General has indicted the ruling body of American Medicine on charges of restraining the activities of group medicine. But if the Medical Association had agreed to play ball with Arnold the indictment would have been shelved. Arnold's system is a brutal combination of the Star Chamber and Nazi bureaucracy. The doctors of America should unite in this fight against a system which jeopardizes the liberties of every citizen.—New York Daily Mirror

## ON THE MEDICAL FRONT

[Charleston S. C. Evening Post Dec 21 1938]

If laymen do not know all the details of the quarrel between the American Medical Association and the Group Health Association, Washington medical cooperative, or of the proceeding which the government has brought against organizations of physicians in the courts of the District of Columbia, they are nevertheless able to understand that the anti-monopoly prosecutions which have been instituted with grand jury indictments may have a far-reaching effect on the practice of medicine and the relations between physicians and patients in this country. Since everybody in the United States is at least a potential patient, the subject is one that concerns all.

Behind the federal prosecution is, of course, the fight of organized medicine against a movement for cooperative medicine and toward socialized medicine. The Group Health Association is a cooperative enterprise that undertakes to provide medical care for government workers who pay regular fees into a central fund for the purpose. The plan attracted national attention some months ago, when at one and the same time the

issue of socialized medicine was debated at the meeting of the American Medical Association and the federal administration named a group to study the subject. It is charged that the defendants in the present case, who include the American Medical Association, several affiliated societies and a number of individual physicians, conspired to "restrain trade" by preventing doctors hired by the Washington cooperative from practicing in the hospitals or consulting with other doctors.

However the Washington case comes out, it is plain that the American Medical Association and its affiliates, which include the overwhelming majority of recognized medical organizations, are certain to feel increasing pressure for socialized medicine of all kinds, an inevitable outgrowth of the political and economic ideas which have been propagated and fostered in the United States in the last few years. Socialized medicine is an inevitable accompaniment of social insurance. When the New Dealers decided to investigate the subject, it was not for the purpose of finding out how to prevent the spread of the idea but rather how to promote it.

What will happen to the art and science of medical practice if and when medicine has been socialized is a matter for conjecture but a good argument could be made out for the claim that when the individual practitioner becomes a salaried worker for the government or a quasi public cooperative, progress in the profession may be retarded, to say the least. What seems fairly certain is that the close personal relationship that has always existed between physician and patient and that many believe is an important element in ordinary medical practice and care will suffer materially and perhaps vanish if the time comes when the doctor is an impersonal agent of government like the inspector of income tax returns or the postoffice clerk. So long as this country is a democracy the people are entitled to have within the limits of the organic law, what they want, but why they should desire to socialize and federalize the practice of medicine is a mystery.

## A STRUGGLE FOR CONTROL OF THE PUBLIC HEALTH

[Philadelphia Evening Public Ledger Dec 22 1938]

Issues of far-reaching importance to the people of the United States are involved in the indictment by a District of Columbia Grand Jury of the American Medical Association and several other medical societies on the charge of participating in an unlawful combination and conspiracy in restraint of trade. It is an extraordinary charge and in many ways unprecedented. It calls the doctors to account under the Sherman Anti-Trust Act, alleging that they intend to make and maintain a monopoly of medical service.

The case, of course, will be bitterly fought to the final decision of the Supreme Court of the United States. Organized medicine, represented by the American Medical Association, recently adopted a resolution that it would fight any such case "to the utmost with every means in its power, exhausting, if necessary, the last recourse of distinguished legal talent."

But on the other side is the plain intent of the Federal Government to establish the principle of group health insurance on its own terms. Many regard this intention as the entering wedge of socialized medicine. Voluntary enrolment of individuals in societies providing medical care is the forerunner of compulsory health insurance under Federal control, probably paid for, in part, with public funds.

The case before the courts is remarkable in many ways. For a long time the fight it represents has been maturing to a crisis. About a year ago the Group Health Association, Inc., was formed in Washington, with its membership restricted to low-income employees of the Home Owners Loan Corporation. Later membership was extended to all Government employees.

But this was an organization unlike many medical insurance groups, about 2,000 of which have received the approval and support of organized medicine. In California, recently, a state program of medical insurance was overwhelmingly endorsed by the profession.

The complaint of the doctors against Group Health Insurance, Inc., was twofold. One objection was that it denied the right of the patient to choose his own physician, requiring him to call on a doctor associated with the organization. The other was that a "third party" intervened between patient and physician, hiring the doctor's skill and services and selling them to the subscriber.

In vigorous terms the men of organized medicine have denounced these characteristics of the plan. They consider them dangerous to the public health, mainly because of the possibility that incompetent practitioners may attach themselves to this type of organization for the sake of the fixed income it offers. They regard them, too, as destructive of the rights and responsibilities of their profession and ultimately of all private medical practice.

So the American Medical Association, the Medical Society of the District of Columbia and the Washington Academy of Surgery thought fit to fight back. They were joined by other medical societies and by a number of Washington hospitals.

Doctors serving the Group Health Association were "disciplined." Some were suspended from membership in medical societies. Some were denied use of hospital facilities. On these grounds, the medical associations are now accused of conspiracy in restraint of trade, an extraordinary charge against a learned profession.

The doctors, therefore, must now defend another point of principle. Dr. William J. Carrington, president of the Medical Society of New Jersey, points out that "organized medicine has always believed that its right to discipline its own members was just as unimpeachable as the right of trade unions to discipline theirs." The principle involved is fundamental, for the code of professional conduct and ethics has bound the men of medicine for centuries and is effective only because there has been power to enforce it. Refusing sanction and approval to the Group Health Association organized medicine had no choice but to put pressure on physicians who defied its disapproval.

This is the case before the court, but a larger issue is before the country. It is not the question whether group health insurance is right or wrong. It is already an established fact. What must now be determined is whether it shall be planned, organized and controlled by the medical profession or by private commercial enterprise and eventually by Government.

### THE MEDICAL "TRUST"

[Atlanta Gr Constitution Dec 25 1938]

Considering the somewhat unrestrained condemnation of the medical profession which emanated from the Department of Justice last summer, the indictment of the American Medical Association by a federal grand jury comes as no startling surprise. Thurman Arnold, assistant attorney general, forecast the procedure. He said, with reference to closing Washington Hospitals to certain doctors affiliated with a group hospitalization plan, that "it is an attempt on the part of one group of physicians to prevent qualified doctors from carrying out their calling."

In the legal eye of the assistant attorney general this was a perfect example of a combination in restraint of trade, punishable under the Sherman anti-trust act. He considered it his duty, presumably, to dissolve the "trust" and punish those responsible for its operation. Hence the indictment.

But when the matter is examined in the cold light of common sense with all the political fog removed, the premise upon which the indictment is based is absurd. The American Medical Association is no more of a trust, or a combination in restraint of trade than Mr. Arnold's American Bar Association, or the national organization of architects, or, indeed, the American Federation of Labor, all of which have prescribed rigid rules of practice.

If a lawyer, or an architect, or a plumber violates the rules of his organization he is chased out at the first meeting, just as a doctor is expelled for practices considered unethical in medicine.

Unfortunately for the idea of a greater expansion of medical services among the people, many shallow-thinking politicians

have jumped to the conclusion that a simple appropriation of \$850,000,000 by the federal government will fill the bill. They labor under the delusion that money can buy anything, that a well equipped office—beautiful furniture, overstuffed chairs and shiny new instruments—means a well equipped doctor.

The profession of medicine, by its very nature, is a monopoly. It couldn't very well be otherwise. It requires at least eight years, from the time he graduates from prep school, to fit a man merely to start "practicing." Additional years are required to make him into a "doctor." So the standards of practice naturally ascend to a high plane. It requires never ceasing vigilance to maintain these standards. If they were altered to fit some particular social theory, the profession would soon be overrun with all manner of smooth-tongued quacks.

It is not denied there is room for broadening and improving the medical care of all the people. The doctors, as a whole, are aware of this. They are willing to cooperate. They are cooperating on a broad front, and in a practical way. The nature of the extensions sought, however, are such as should call for making haste slowly. It must first be decided just what is to be done.

Therefore the indictment under the assumption that a certain pet scheme in Washington to revolutionize medical practice is everything to be desired will, in all probability, do more to retard than to hasten the movement.

From the Evening Star Washington D C Dec 23 1938

### A M A INDICTMENT

[The Dallas Morning News Dec 22 1938]

Certainly open to serious question is the legitimacy of the indictment brought against the American Medical Association and certain of its officials and groups for violation of the anti-trust laws. Medicine and surgery do not constitute trade in the ordinary meaning of the term. A conviction can do no good and an acquittal, highly probable, may deter the reforms in medical practice which the group health association movement seeks to effect.

Fearful of the state medicine boggy and apparently wilfully blind to the successful operation of contract medicine in Great Britain the A M A has long set its face sternly against any effort to solve the problem of medical care cost on a pre-contract group basis. The A M A has certainly sought to discipline the ethical doctor and prevent his serving the sort of practice to which it objects regardless of his standing as a practitioner.

In all probability the best cure for that would be found in statutory regulations which would protect those physicians who seek to cooperate in group health experiments. The present A M A case is by no means comparable to ordinary trust suits, for the association will not deny the acts recorded in the

complaint except in the interpretation made of them by the grand jury. But the A. M. A. can itself be disciplined without criminal proceedings for acts which the organization does not regard as criminal or even as wrong.

As a matter of fact, of course, all signs point to voluntary agreement by the medical field to experiments from which it has long shied so violently. Group medicine plans for low or medium income bracket patients are now being studied and in some cases tried by medical societies. The affected public believes medicine has long been in error in its attitude. But it knows the doctors are not criminals and it believes that medicine can be trusted to set itself right.

### Chimney Surgery—By Hungerford

From the Pittsburgh Post-Gazette Dec. 22, 1938

### MEDICAL CHARGE

[The Indianapolis News Dec. 22, 1938]

The indictment at Washington of officials of the American Medical Association and members and officials of local medical societies in the District of Columbia indicates that the department of justice has not receded from its position that the anti-trust laws were violated when the medical groups used their power to obstruct the formation and operation of a group health association in Washington. This association was formed by government employees. In return for monthly dues they expected to receive medical and hospital service. The government contends that the medical societies in Washington opposed this move by barring physicians who were retained by the group health association from their organizations and from recognition as hospital staff members.

The American Medical Association has declared that it will defend itself and its members on two basic grounds. Their first defense is that the anti-trust laws are directed against monopolies in restraint of trade, while the practice of medicine is in no sense a trade within the commonly accepted meaning of the term. Their second line of defense is that they have opposed these organizations because they tend to throw control of the

practice of medicine into the hands of the laymen who direct the group. They have indicated that they are not opposed to group health organizations which give full recognition to the right of physicians to make their own professional decision.

In prosecuting this case, the department of justice will have to pioneer in a field which heretofore has never been regarded as affected by the anti-trust law. The right of professional groups to organize for the purpose of protecting their profession from unworthy practitioners and from methods which are deemed to be adverse to the public welfare has always been respected. If the government's position is sound every organization of professional and skilled workers will risk similar action. Certainly trades unions which insist on high standards of skill as a condition of membership will face the possibility of having to defend their organizations. The question goes to the fundamentals of personal liberty under the American system of free enterprise.

### MEDICINE ON TRIAL

[Grand Rapids Mich. Press Dec. 22, 1938]

Federal indictments against the American Medical Association, three medical societies and twenty-one individuals charging violation of the anti-trust laws have thrust before the American people a subject of deep significance.

Legally the case reaches down into the fundamental meaning of professional service. Is medicine to be considered a profession or a trade? Is medical service to be dispensed like an ordinary commodity or will it continue to be regarded as a service, the professional and ethical standards of which shall be regarded as above the ordinary rules of trade and commerce?

It may not be possible for the government prosecution to limit medicine with trade and commerce from a legal standpoint. But apparently it is to be the principal defense at the outset. But even though a successful defense may be made on these grounds it will not solve the problem which now confronts the profession.

If medicine and trade are closely connected in the public mind it is indicative of a grave development of public thought. If the practice of medicine is not to be regarded as based on ideals of highest service to the community, but rather on a foundation of pure commercialism, is there not a serious threat of deterioration in standards of practice? The average medical man probably would answer that question in the affirmative.

How far the public mind has progressed toward this concept is indicated in part by the fact that a grand jury of twenty-three laymen approved the indictment. The Grand Rapids Press bureau in Washington reports that this jury was made up of salesmen, business executives, managers, a grocer, a truck driver, engineers, merchants and a Negro messenger. The group which decided there was evidence sufficient for indictment was not drawn from any one class of citizenry. It was a diversified group. And while the grand jury did not decide whether medicine is no more than a trade, it was convinced nevertheless that indictments were warranted under laws which forbid conspiracies "in restraint of trade or commerce." It would appear that in these laymen's minds, at least, the distinction is not sufficient to be a bar to action.

The medical profession might properly conduct a searching inquiry into its own practices in an effort to discover why this has come about. Has it been because of a failure to reach and retain the respect of large masses for the standards and position of the profession?

It may be possible for the A. M. A. and others under indictment to beat this case on the ground that the profession does not fall within the scope of the law. But there must be a frank answer to the specific charges as well if public confidence is to be retained. The profession as represented in the A. M. A. has been accused of using its power to force members to abide by its rules against engaging in group medical projects, it is accused of practicing professional ostracism to restrain cooperation with the groups and of forcing hospitals to close their doors against those who do not comply.

Perhaps the answers to these charges are easily made. Perhaps the medical association can refute the accusations completely or explain them satisfactorily. That is what it

should attempt to do. It should not seek to evade these answers by taking refuge behind a purely technical defense, for the charges have raised questions in the public mind to which the general public will expect replies. Medical men close to the A M A declare these suits are merely the climax of the fight between those wishing to provide a lower standard of medical care and those trying to maintain a higher standard. The public must be informed of the issues, however, if fair judgment is to be passed.

It is worthy of note also that the same practices charged against the A M A have been followed by other organizations, notably union labor, without drawing the fire of the department of justice. Workers declining to join unions have been ostracized. The monopoly in certain labor markets has not been challenged by the government. It seems to make a difference who follows these alleged practices.

Out of all this turmoil there ought to come a better understanding of organized medicine. The gain may not be all on one side. The whole question of a wider distribution of medical care and a more even distribution of its costs may be reviewed before this case is settled. That should be all to the good unless the forces of prejudice are allowed to take control.

## MEDICINE AND THE LAW

[Minneapolis Journal Dec 23 1938]

The American Medical Association three local medical societies and twenty-one individual physicians are now under federal indictment charged with violation of the Sherman Act. The indictments charge interference with spread of group medical practice. They mean criminal prosecutions—a government big stick.

Whether socialized medicine or group practice are desirable social objectives are questions still open to debate. Highly complex, they are receiving the profound study of some of the best minds in the profession itself. But assuming for the moment that they are, is criminal prosecution of medical leaders the way to accomplish those ends? To ask the question is to answer it.

This is not to say that wider distribution of the best medical service is not desirable. Doctors themselves do not deny that there are great numbers of people who, through ignorance, improvidence or any one of a dozen causes, are living on decidedly substandard levels medically speaking. Clinging and prosecuting the medical profession, however, is not the way to bring these groups to higher standards.

In the last five years the profession itself has shown its willingness to attempt a solution of the knotty problem of medical economics. Beginnings have been made in many communities and some states. These, without exception, have been on medicine's own initiative. They have been brought about largely by the pressure of changing social and economic forces, and the doctors' knowledge that we live in an age of ferment and new departures. Coercion seems wholly unnecessary.

## INDICTING THE DOCTORS

[Springfield Mass Union]

The American Medical Association three other medical societies and twenty-one physicians have been indicted by a Federal Grand Jury for violation of the Sherman Antitrust Act. A first impression, and one which the public will undoubtedly share quite generally, is that the Department of Justice has used a butcher's cleaver where a tempered blade would be more suitable for the purpose.

That purpose is to forward the Government's group insurance program to do which it is willing to frighten and malign highly respected medical associations and a distinguished group of able and honorable physicians and officials. We have in this roughshod procedure one of the best examples yet produced of the New Deal's reckless and ill considered methods of achieving its ends.

This is entirely aside from the merits of the question in dispute on which there are sincere and legitimate differences

of opinion. There is much to be said for group health projects, and those who believe in them are enthusiastic in their determination that a plan be adopted under government auspices. Nor is the American Medical Association entirely opposed to group health in principle. What this highly respected association of distinguished medical men insists upon is that thorough study shall first be made of plans which can be made to work effectively and efficiently with a minimum of Federal control.

The medical profession is working out plans that will be practicable and equitable. They require time. The present Administration has given us many examples of hasty experimentation which have worked out badly and proved costly. In the field of medicine the more scientific approach is not only desirable but imperative, because the public welfare is vitally concerned.

## LOOKING INTO THE PHYSICIANS

From the New York Times

## THE DOCTORS ARE INDICTED

[New York Herald Tribune Dec 22 1938]

With his indictment of the American Medical Association and its eminent officers together with its District of Columbia affiliates and several of the leading physicians of Washington Mr. Thurman W. Arnold has fired the second gun of his campaign to regulate the vexed question of "group medicine" through the unlikely instrument of the anti-trust laws. The ordinary American entertains, we believe, a high respect for the medical profession as composed in general of men of exceptional unselfishness, competence and devotion. When he thinks of it, he probably admires its powerful official organization—represented by the American Medical Association and its local societies—for the probity with which it has maintained ethical and technical standards and policed the profession against quackery and venality. It will be difficult for Mr. Arnold to convince the public that American physicians are a greedy crew and their organization a selfish monopoly primarily interested in the ruthless suppression of competition.

On the other hand, the ordinary American is coming to regard the leadership of the medical association as inclined to err rather heavily on the conservative side in facing the real problems underlying the economics of medical care in the contemporary

world. He is being led to doubt whether that leadership is fully representative of the most alert thought among physicians themselves on this social and economic side of medical care, and if the facts should tend to sustain Mr. Arnold's allegations of a fairly ruthless suppression, in the District of Columbia, of a possibly hopeful experiment in voluntary group medicine, it would be difficult for the American Medical Association to convince the public that its action was either wise or allowable.

The anti-trust laws seem to us a most unsatisfactory instrument wherewith to raise this issue. If, as he hopes, Mr. Arnold gets a consent decree regulating the Washington situation alone, it will leave the Department of Justice with a kind of discretionary power over medicine it is hardly competent to exercise. If the case is fought through the courts, as the medical association promises that it will be, it must end either in a victory for them, which would leave everything as before, or a defeat which might very gravely jeopardize their invaluable function of generally policing the profession. Now, however that the battle has been joined, it will have to be fought out and perhaps the air will be somewhat clearer when it is over.

## "DOC" INDICTED

[New York World Telegram Dec 21, 1938]

"Organized Medicine Indicted as Trust," says headline

Which gets into a big subject, very big, indeed—one that touches not only every doctor but every other son of man who has been afflicted with any ill to which flesh is heir, from belly-ache to coronary thrombosis.

For some reason or other the headline reminds us of a story, attributable, if our memory serves us right, to the late Lincoln Steffens.

The devil, as the story goes, grew alarmed at a report that sin wasn't doing so well in a certain remote community of his realm. He sent a lieutenant to investigate. The report returned, after careful inspection, was that not a gram of evil could be found.

"Is that community organized?" asked the devil.

"No," replied the emissary.

"Well that's what's wrong," said the devil. "Organize it!"

This is an age of organization. And organization up to a point is essential in as intricate a civilization as ours. But

organization can become too refined—whether it be organized business, organized art, organized labor or organized professions, whether the National Association of Manufacturers, the American Federation of Labor, the Congress for Industrial Organizations, the New York Stock Exchange, the American Bar Association or the American newspaper publishers.

So the real test in this suit against the American Medical Association and its allied units is—Has organization gone too far—has the economic aspect been exalted under the guise of professional ethics to a point where, as the indictment alleges, the peace and dignity of the United States of America are threatened?

Without seeking to try the case or to restate all the issues set forth by the District of Columbia Grand Jury, we do want to say this about 'Doc'—

Whether he be on one side or the other in this controversy between the American Medical Association and the group health associations, we think that medicine, of all occupations, is least motivated by the acquisitive impulse. We've all needed Doc. We all have been willing to give our shirt and the fillings from our teeth if he would only come right now, and then we all have kicked about his bill if it was more than \$2 after we got well.

The very nature of his work—the strange ambition which makes one human being want to spend seven or eight years learning the anatomy of other human beings in order to keep their microbes on straight—has always been a mystery to us. From the old country doctor to the most modern and steam-heated specialist its service that can't, by its very nature, be essentially mercenary. Commercially you could go farther and acquire more, applying the same amount of energy and intelligence, in the shoe business, where the telephone doesn't ring in the middle of the night.

But maybe this inherently noble vocation has, as the Steffens story puts it, become overorganized.

Anyhow, that's the question in this antitrust case.

## POINT NOT WELL TAKEN

[Louisville Ky Times Dec 21, 1938]

"It is indicted," says a Washington dispatch, "that the American Medical Association may carry the case to the United States Supreme Court, if necessary, with the contention that its operations cannot be restricted by the Sherman Act since medicine is not a trade, but a profession."

The whole question of what should be done to give Americans, instead of a small class of Americans, good medical service is baffling.

The Times is not inclined to rush in with a solution.

But if the American Medical Association should go to the Supreme Court with the contention that its operations cannot be restricted by the Sherman Act, and if at the same time those operations should be by popular verdict, declared antisocial, a law might be found to restrict the American Medical Association.

Laws are mutable.

No group of citizens, with a learned profession as their shield, could long withstand public sentiment if it were believed that their attitude blocked what promised to be a practical plan to broaden the services of medical and surgical science.

The fundamental question is how those who are neither rich nor extremely poor can get medical service, and how medical service for the poor may be so improved that it will not repel rather than attract those whose lives may depend upon accepting it.

That is a much larger question than whether a physician is subject to regulation under an act designed to regulate business.

The question is one of the largest which thoughtful Americans are considering.

Legalistic argument cannot be brought to bear effectively in the circumstances. A battle, hardly a war, might be won on a technicality in such a situation.

## THE STORY OF THE INDICTMENT

*Chronologic Record of Events Leading to the Indictment of the American Medical Association Because of the Difficulties of the G H A , Inc*

In the Annual Report of the Twentieth Century Fund, Inc, for 1936, appears this statement

"As a result of the activities of the Fund, and of the Health Economics Association, substantial progress has been made in the promotion of voluntary, cooperative, group payment medical service organizations. At the end of the fiscal year twelve agencies of this kind had actually been organized, consisting mostly of small groups. A total of nine other organizations were definitely committed to such plans, of which one is actively engaged in establishing a plan and the others are in various stages of negotiations with organization officials and employees. Chief among these groups is the employees in the District of Columbia of the Home Owners Loan Corporation."

The Twentieth Century Fund, Inc, was organized under a Massachusetts charter in 1922 as a successor to the Cooperative League, which had been organized in 1919 by Mr Edward A Filene. In 1936 Mr John H Fahey was chairman of its executive committee.

Again in 1937 the report of the Twentieth Century Fund said

"The most important project assisted by the Association in 1937 was the organization set up by the employees of the Federal Home Loan Bank Board to furnish, on a periodic payment basis, practically complete medical services for themselves and families. These employees formed the Group Health Association, Inc, a non profit organization, chartered by the District of Columbia specifically for this purpose.

"This group started to furnish service on November 1, 1937, to approximately one thousand employees and their families. It now has a list of twenty-seven hundred subscribers who, with their families represent a membership of approximately ten thousand individuals. The Group Health Association has an income which amply meets its expenses in furnishing this service. This group has been subjected to severe attacks from the local medical association, as well as from certain District officials."

Early in 1937 there began to be circulated in Washington, D C, a prospectus marked "Confidential For Private Circulation Only," entitled "A Plan for a Cooperative Medical Service on a Periodic Payment Basis for Federal Employees and Their Families in Washington." It was indicated that attempts would be made to obtain the cooperation of members of the Medical Society of the District of Columbia, that the Medical Society of the District would be invited to appoint a representative to sit with the committee in establishing the plan, and that an advisory committee of physicians would be appointed to aid the medical director on relevant matters.

On February 24, 1937, the Group Health Association, Inc, filed its certificate of incorporation, and in March 1937 two members of the staff of the Home Owners Loan Corporation, Messrs Russell and Zimmerman, were directed to prepare and present a definite outline for procedure for consideration by the board of directors. Thereafter Horace Russell, general counsel of the Home Owners' Loan Corporation, in March, sent to the Corporation a resolution authorizing a contract between the Home Owners' Loan Corporation and the Group Health Association, Inc. This contract was executed on March 22, 1937. It must be remembered that Mr John H Fahey, chairman of the executive committee of the Twentieth Century Fund, Inc, was also chairman of the Board of Directors of the Home Owners' Loan Corporation. As part of the details of

the contract, the Home Owners' Loan Corporation agreed to pay to Group Health Association, Inc, \$10,000 on request and, beginning on the date of the establishment of its service, the sum of \$833.33 monthly in advance for a period of twelve months, and thereafter the sum of \$1,666.67 per month for the next twelve months. Thus was created the appropriation of \$40,000 of government money for the financing of a private corporation to provide medical services in the District of Columbia. The interlocking character of the arrangement was further established by a stipulation which provided that two of the five members of the executive committee of the Group Health Association, Inc, would be nominated by the Federal Home Loan Bank Board and that the by-laws of the Association would be satisfactory to the Corporation.

Attempts were made by the Chairman of the Economics Committee of the Medical Society of the District of Columbia and by the director of the Bureau of Legal Medicine and Legislation of the American Medical Association to find out the details of operation of the Group Health Association, Inc, the details of the contract and other data necessary to determine the lawfulness of the arrangement. Incidentally, unlawfulness at that time was impliedly admitted later by the Association through changes in its by-laws which were apparently made for the purpose of attempting to bring it within the law.

In November 1937 the question of the legality of the practice of medicine by a corporation was raised and various attorneys expressed varying opinions. Then on Nov 20, 1937, counsel for the Medical Society of the District of Columbia submitted to the United States Attorney in and for the District of Columbia and to the corporation counsel for the District of Columbia a brief showing that Group Health Association, Inc, was engaged in the practice of medicine and in the business of insurance.

The publicity associated with these legal procedures was followed by an attempt by members of the Senate and Congress of the United States to determine the legality of the diversion of the funds of the Home Owners' Loan Corporation to the use of Group Health Association, Inc. In December 1937 Senator McCarran requested the acting comptroller general of the United States to inform him as to the authority of law under which public funds had been diverted from the Home Owners' Loan Corporation for the purpose of establishing a social health organization among the employees of the corporation. Then acting comptroller general, Mr R N Elliott, replied

"It has been the long-established rule in the Federal service that the functions of the agencies of the United States are restricted to those activities authorized by general or special enactments of the Congress, and where an activity involves the expenditure of moneys of the United States, the appropriation laws must make the moneys available therefor in no uncertain terms if such activity is to be accepted as lawful. Accordingly, it must be concluded in the instant matter that the disbursements and other costs were made and incurred without authority of law."

With this opinion, the legal department of the Home Owners' Loan Corporation differed. However, a sub-committee of the Committee on Appropriations of the

House of Representatives gave hearings on the Independent Offices Appropriation Bill 1939, in which appropriations for the Home Owners' Loan Corporation in relationship to Group Health Association, Inc., came up for consideration. The diversion of funds for this purpose was defended by Mr. Russell, general counsel for the Home Owners' Loan Corporation. The board might, Mr. Russell thought, provide dental services and in fact do whatever in its judgment was necessary for the accomplishment of its major purpose. To which Mr. Woodrum of Virginia, chairman of the subcommittee, replied:

"As long as I have been a member of the Appropriations Committee I have never heard any department advance that sort of philosophy to the Appropriations Committee."

Mr. Woodrum continued:

"Entirely separate and apart from the merits or demerits of the proposition that you have announced or whether there should or should not be group insurance and medical treatment and entirely from the standpoint of congressional supervision and control of appropriations and expenditures I have never understood, nor do I think it is the law or by any possible wide stretch of the imagination that a department can have money appropriated for it have hearings and come back and justify expenditures for something entirely foreign and separate and apart that was not in the minds and certainly could not have been in the minds of any member of this committee or the Budget when they passed upon this appropriation of \$40,000 which, of course relatively speaking is insignificant. It is the principle of the thing."

"If you should come back next year with some like proposition entirely separate and apart I should feel that it is a perfect farce for a committee to sit here and undertake to go over the appropriations and discuss what you should spend your money for if next year you are coming here and say 'Oh, sure. We did that, but we have general power to spend our funds for anything that the board determines is of vital interest to the Corporation. I don't understand your view about the law, and certainly that is not the ruling of this committee.'"

The publicity associated with the promotion of Group Health Association, Inc., indicated promptly that it had the support of many of those associated with the federal government.

In May 1938 Attorney General Cummings of the Department of Justice explained in a press release that the Department of Justice proposed to undertake certain prosecutions under the antitrust laws and that a series of public statements would be issued throwing light on the policy. One of the statements to be given out, it was said, would be to call the attention of Congress to the interpretation and application of antitrust laws by the Attorney General as they might have a bearing on contemplated legislation. From this time on came the series of peculiarly timed releases to the press from the Department of Justice associated with the endeavors of the federal administration to support Group Health Association, Inc. Thus on June 1, 1938, the *Evening Star* of Washington, D. C. announced that:

"The Department of Justice has launched an inquiry into complaints that the American Medical Association and the District of Columbia Medical Society have violated Federal anti-trust laws in connection with their fight against 'group health' plans."

"The inquiry is being made by the anti-trust division of the department, under the direction of Assistant Attorney General Thurman Arnold, recently appointed by President Roosevelt as the administration's chief trust buster."

"It is understood the complaints, presumably from interests associated with or defending Group Health Association, Inc., of the Home Owners' Loan Corp., charged that alleged obstructionist tactics adopted by the District Medical Society and the

American Medical Association are in conflict with anti-trust laws forbidding 'combinations in restraint of trade.'"

On June 3 a representative of the American Medical Association called at the Department of Justice to ascertain the basis for the foregoing statement. The statement was given out for publication, it was learned, on the basis of a call at the office of Mr. Thurman Arnold, Assistant Attorney General in charge of the Antitrust Division by one man who requested Mr. Arnold to have the Department of Justice intervene in the controversy between Group Health Association Incorporated and the Medical Society of the District of Columbia. The caller filed no formal complaint and the statement given out was based, it appeared, entirely on the verbal request of the caller. The name of the caller was not disclosed.

This announcement immediately preceded the meeting of the House of Delegates of the American Medical Association in San Francisco on June 13.

#### ANOTHER RELEASE FROM THE DEPARTMENT OF JUSTICE

On the last day of the meeting of the National Health Conference, July 20, the Department of Justice presented to the press another of its releases. On that day it released to the press a statement concerning a petition in equity that it had filed against the major motion picture companies, their associated and subsidiary companies and numerous individuals connected with the industry under the Sherman Antitrust Act. In making this announcement the Department of Justice undertook to justify its failure to proceed against these corporations and individuals, by criminal prosecution, saying:

"One reason for determining to proceed first in equity rather than criminally is therefore, the fact that only an equity decree can accomplish the result which the Department believes to be essential."

"A further reason for instituting equity rather than criminal proceedings at this time should be noted. In the course of its study of the motion picture industry the Department attempted through the voluntary cooperation of the major producers, to adjust the difficulties of independent exhibitors who brought their problems to the Department and who consented to such a course. The Department believes that in the light of its dealings with the industry in the past, it would be inequitable to institute a general criminal proceeding relating to the general subject matter of this suit."

"The Department desires to encourage and not to retard the development and orderly operation of the motion picture industry."

Leslie C. Garnett, United States District Attorney for the District of Columbia, and his successor in office, David A. Pine, recognized the fact that Group Health Association, Inc., was practicing medicine in violation of law and indicated an intention to prosecute. J. Bach Moor, Superintendent of Insurance for the District of Columbia, recognized that the association was engaged unlawfully in the business of insurance and he likewise threatened prosecution. Representatives of Group Health Association, Inc. in order to avoid these criminal prosecutions, petitioned the District Court of the United States for the District of Columbia for a declaratory judgment in which the court might express its opinion as to the legal or illegal character of the activities of the Association. The court, through Justice Jennings Bailey, rendered a memorandum opinion, July 27, 1938, to the effect that—

"I see no reason why an individual may not, without violating the statute, contract with a physician for medical services for a stipulated period at a fixed compensation, and it would seem

that a group of individuals might make the same arrangement with a group of physicians. It would seem that this group of individuals might incorporate themselves for their own mutual benefit for the same purpose. Such a corporation, not for profit but for the mutual benefit of its members, is in my opinion not engaged in the practice of medicine or in holding itself out as doing so. It is true that a corporation can act only through its agents and employees, but the physicians with whom the plaintiff makes contracts are rather in the position of independent contractors, and the plaintiff does not in any way undertake to control the manner in which they attend or prescribe for their patients."

With the contract between the Home Owners' Loan Corporation and Group Health Association, Incorporated, whereby the association agreed to provide "substantially complete medical and hospital service to such employees of the Home Owners' Loan Corporation as care to join it on a reasonably monthly basis" Justice Bailey found more difficulty, but he concluded that the contract for such service did not constitute the practice of medicine. With those provisions of the contract between the Home Owners' Loan Corporation and Group Health Association, Incorporated, whereby the association agreed to provide physical examinations at the time of employment of all new employees in the Washington office and to manage and supervise the emergency rooms and the employees in the nursing service maintained in connection with such emergency treatment and in visitations to employees of the Washington office who are on sick leave, Justice Bailey did not concern himself. He rejected citations to cases bearing on the right of corporations to practice law, saying that they were "not closely analogous, they being based on the common law and governed by the courts independently of any statute." Justice Bailey concluded that Group Health Association, Incorporated, was not engaged in the practice of medicine but gave no citation to any decision tending to support that position. Similarly, and apparently for the sole reason that he believed that the word "payment" "as ordinarily used" means the payment of money, Justice Bailey held that Group Health Association, Incorporated, was not engaged in the business of insurance. It undertook to discharge its obligations in services and not in money. Consequently, on July 29, 1938, the court entered a decree to the effect stated above. The Superintendent of Insurance for the District of Columbia and the United States District Attorney noted an appeal to the United States Court of Appeals for the District of Columbia, which appeal was allowed. It is understood that the United States District Attorney did not perfect his appeal. The Superintendent of Insurance for the District of Columbia, it is believed, is pursuing his appeal from the judgment of the District Court that held that Group Health Association, Incorporated, is not engaged in the business of insurance.

On July 30, Assistant Attorney General Thurman Arnold released in Washington, for the morning papers of August 1, a statement of what he said were the results of "A preliminary investigation made by the Department of Justice in response to numerous complaints with reference to activities within the medical profession in the District of Columbia." He alleged that the Medical Society of the District of Columbia, the American Medical Association and some of the officials of both these organizations were attempting to prevent Group Health Association, Inc., from functioning and he stated what he said were the methods that had been used to accomplish that end. This,

he said, was a violation of the antitrust laws, because in the judgment of the Department of Justice those laws prohibit "combinations which prevent others from competing for services as well as goods [sic]." The persons responsible for this alleged attempt to prevent Group Health Association, Incorporated, from functioning could be ascertained, Mr. Arnold said, only by a grand jury investigation, and such an investigation would be undertaken in the near future. He ignored the apparent availability of civil proceedings, such as the Department of Justice seemed to deem sufficient in dealing with the motion picture industry in a situation similar to that in which Mr. Arnold undertook to place the medical profession. Assistant Attorney General Arnold undertook to discuss the economic conditions of medical practice in the United States, apparently as a basis for his proposed prosecution. He stated that, "In the event that voluntary cooperation results in constructive proposals going *beyond the elimination of illegal practices*, the Department will adhere to its previously announced policy of submitting such proposals to the court as a basis for a consent decree." How far "beyond the elimination of illegal practices" such supposedly voluntary cooperation would have to go to meet Mr. Arnold's wishes he did not state, but it is known that in one of the latest drafts of his newspaper release it was stated that such so-called constructive proposals would have to go "far" beyond the elimination of illegal practices.

On August 12, Sterling Ruffin, M.D., Prentiss Willson, M.D., and Elijah W. Titus, M.D., in their respective individual capacities as licensed physicians in the District of Columbia, filed a bill of complaint against the Group Health Association, Incorporated, in the District Court of the United States for the District of Columbia, praying that Group Health Association, Incorporated, show cause why it should not be enjoined and restrained from engaging in the practice of medicine and surgery in the District of Columbia and praying that, pending the final hearing and determination of the cause and thereafter, Group Health Association, Incorporated, be enjoined and restrained from doing any act, or holding itself out to do any act, which constitutes the practice of medicine and surgery in the District of Columbia.

On August 19, Assistant Attorney General Thurman Arnold broadcast an address over the Columbia Broadcasting System, entitled "The Antitrust Laws, Their Past and Future." He said, in part:

"The American Medical Association, by use of various types of pressure, declines to allow a patient to be admitted to a hospital unless he is attended by a member of that association. The Department, of course, would regard as reasonable attempts of the medical association to require the highest standards. What they are doing, however, is to prevent qualified physicians from practicing their profession in hospitals because they disagree with their social views as to the best method of furnishing medical care to the poor. They have expelled a physician who was associated with Group Health and reinstated him when he dropped that association. The Department is not interested in Group Health or in any particular form of labor organization or in the encouragement of any particular industry. It is only interested in insuring equal opportunity for all qualified persons to compete in either rendering services or selling goods excepting in those cases where Congress decides otherwise by special exception to the antitrust laws."

Mimeographed press releases of this address were issued in Washington.

On August 26, a representative of the Bureau of Investigation of the Department of Justice called at the offices of the American Medical Association, in Chicago, and reported that he had been sent to look over the files of the Association. He was told that the office was open to him and thereafter proceeded to examine carefully the files of the Bureau of Legal Medicine and Legislation, the Bureau of Medical Economics and the Council on Medical Education and Hospitals. He took away with him from time to time documents from the files, for the purpose of having them photostated for the use of the Department of Justice. The originals were returned.

On October 1 Assistant Attorney General Thurman Arnold delivered an address before the Missouri Bar Association, at St. Louis entitled "The Enforcement of the Sherman Act." Press releases were issued in Washington by the Department of Justice. Concerning the American Medical Association, Mr. Arnold said:

"Forty years of sporadic enforcement of the antitrust laws has prevented our forming a body of precedents with respect to particular industries. This has created a vicious circle which runs as follows: 1. It is not fair to enforce the antitrust laws in cases where their application is not clear. 2. At the same time the application never becomes clear because the cases are not brought before the court.

"Let me give an example which has caused wide comment in the press—a grand jury investigation of the use of coercion and boycott by members of medical societies. I will cite a typical instance of the kind of complaints which gave rise to this investigation. A physician was under contract with a corporation to care for its employees. He was a member of the medical society in his community, in fact he was a vice president. Nothing was ever said by any medical group against this very praiseworthy attempt of the corporation to further the interests of public health. This physician signed a contract with a labor union in almost identical terms with the contract which he already had with the corporation. The following consequences ensued: (1) He was expelled from his medical society, (2) the medical society by threats and pressures attempted to close hospitals against him. He was a fighter. He could not understand how in a free country he should be excluded from practicing his profession because of his views on how to distribute medical services so long as no medical standards were involved. He succeeded in retaining privileges in one hospital. His practice was crippled but not stopped. Thereupon members of the medical society approached the insurance companies which protected him against suits for malpractice. They succeeded in getting his policies canceled. The doctor was amazed at this sudden turn of events, but he was not of the stuff that yields to such un-American methods. He took out insurance in Lloyds in England at double the rates. He still has his head above water, but at a terrific cost.

"The private organization which did these things acted on the sincere belief that they had the right to enforce their views against contract practice by boycotts and coercion of third parties. Most of them never thought of the antitrust laws. Those who did think of them were informed that they did not apply to physicians for reasons which had been urged and rejected in England twenty years ago.

"The reason for this confusion was that no case had ever been brought before to determine whether this simple and direct form of coercion was a peculiar privilege of physicians. England had settled the question holding such practices on the part of the British Medical Association a conspiracy in restraint of trade. Here, no case had ever been brought.

"The confusion about the purposes of the antitrust laws after half a century of neglect is illustrated by a resolution passed by the American Medical Association at its last meeting with respect to the grand jury investigation. It declared it was not a monopoly and denounced attempts to treat it as such.

"Yet the essence of the charge against the medical society is not that it is a monopoly but that it is guilty of illegal restraints

and coercions. Others equally confused thought that the Department of Justice was advocating group health. It has no interest in group health or in any form of medical care. Its interest is in preserving the freedom of qualified individuals to pursue their calling without the fear of a secondary boycott. The Department believes that, out of this freedom to compete and experiment, the medical problem will be solved in an American way. It has no interest in whether medical societies take a liberal or reactionary attitude. It desires freedom of individuals to take any attitude.

On the same day as that on which Assistant Attorney General Arnold attacked the medical profession in St. Louis, the Department of Justice, through Charles Pearce, Special Assistant to the Attorney General, made a similar attack before the Sixteenth Annual Fall Conference of the New York Women's Trade Union League, under the title "Monopoly and Medical Care." Mimeographed copies of the Department's attack were issued in Washington. The address is most aptly described as a diatribe against the medical profession. It carries with it the usual invitation for the medical profession to come to the Department of Justice with a draft of a proposed consent decree, saying—

"In such a situation the Department has no alternative except to proceed before a grand jury unless special considerations render a criminal proceeding inequitable."

On October 4, the United States Attorney for the District of Columbia filed in the office of the Clerk of the District Court of the United States for the District of Columbia a certificate or petition for the impaneling of an additional grand jury before which certain special assistants to the Attorney General might conduct an investigation into alleged violations of the Sherman Antitrust Act. On the same day the chief justice of that court entered an order for the impaneling of such an additional grand jury.

On October 17 the additional grand jury impaneled under the order of the court of October 4 was instructed by Mr. Justice Proctor of the District Court of the United States for the District of Columbia.

Later in October a subpoena was received from the District Court of the United States for the District of Columbia, calling on the American Medical Association to appear before the Additional Grand Jury, in Washington, D. C., November 2, with certain documents specified in the subpoena. Dr. William C. Woodward, Director of the Bureau of Legal Medicine and Legislation of the American Medical Association, presented himself at that time, with the documents called for. By advice of counsel, he declined to waive his right to immunity that would arise if he testified. He therefore was not allowed to appear and testify or even to present the documents. He returned with them to the headquarters of the Association. Thereafter Dr. W. W. Bauer, Director, Bureau of Health Education, appeared before the Grand Jury and presented the documents called for.

On November 3 a second subpoena issued by the clerk of the District Court of the United States for the District of Columbia was served on the American Medical Association, directing it to appear before the Grand Jury in Washington, D. C., November 21, and to bring with it numerous documents named in the subpoena. On November 10 the American Medical Association filed in the office of the clerk of the court a motion to quash the subpoena.

On November 7 the Department of Justice, in a press release at Washington, D C, under the title of "Antitrust Laws Consent Decrees Presented by the Government in the Automobile Finance Cases," said

"Antitrust prosecution will not be compromised upon mere agreement to cease the practices complained of. This would constitute nothing more than the exercise of executive forgiveness for an offense already committed. However, if a voluntary plan is submitted by defendants, which not only eliminates the practices complained of but goes farther and offers provisions in the public interest, designed to create a more orderly market and to prevent a repetition of violations in the future, it will be considered as a ground for recommending a *nolle prosequi*.

"The test of whether a *nolle prosequi* will be recommended on the basis of a consent decree is whether that decree accomplishes more in effectuating the purposes of the Sherman Act than could be obtained through the criminal court."

On November 10 the Department of Justice, through special assistant to Attorney General Wendell Berge, reported to the Fifth Annual Business Convention of the American Finance Conference, on "Consent Decree Policy in Antitrust Suits." This report is important as indicating the extralegal ends sought by the Department of Justice, through actual and implied threats of criminal prosecution under the antitrust laws. Mr Berge said

"The criminal proceeding cannot be used to coerce any kind of consent decree. Nor can the government, when a criminal case is pending concurrently, make compromises or engage in bargaining in order to induce the inclusion of certain decree provisions in return for the concession of others. If, however, parties who have been indicted are willing to offer constructive proposals which are in the public interest and which go beyond what the law requires and beyond anything that might be achieved through successful criminal prosecution, the Department can always receive and consider such proposals and if it deems them in the public interest can submit them to the court for consideration as a basis for settlement of the controversy. If decrees which have been thus voluntarily proposed by the defendants are accepted by the Department they may be submitted to the court with the recommendation that the indictment be *nolle prosequi*. The vital question in such a situation is whether the proposed decree goes so far in promoting the public interest that the Department is warranted in recommending dismissal of the criminal proceedings.

"Moreover, when criminal proceedings are pending, the Department will always reject consent decrees which merely eliminate unlawful conduct. It is not enough when parties have been indicted that they shall promise never to break the law again. Officers charged with the enforcement of criminal laws cannot dismiss proceedings upon the simple promise of the parties to be good. The only consent decrees which the Department is willing to consider during the pendency of a criminal case are those containing provisions for affirmative public benefits which could not be secured by the criminal proceeding alone.

On November 17 Justice Proctor of the District Court of the United States for the District of Columbia quashed the first and second paragraphs of the second subpoena and allowed the third paragraph to stand.

On or about November 23 a third subpoena was issued by the District Court of the United States for the District of Columbia, calling for certain additional documents. This subpoena was served on counsel for the American Medical Association in Washington, D C, and on the same day the Association filed a motion to quash it. The court denied the motion. Thereafter the American Medical Association, by Dr W W Bauer, Director, Bureau of Health Education, appeared before the Additional Grand Jury and

delivered the material described in the third paragraph of the second subpoena and all matter described in the third subpoena.

On December 1, notwithstanding the fact that the Additional Grand Jury in Washington was hearing evidence concerning the alleged violation of the antitrust laws by the American Medical Association, the Department of Justice released to the press in Milwaukee by a special assistant to the Attorney General, Douglas Maggs, in a symposium in which Dr Kingsley Roberts and Dr Morris Fishbein participated. Mr Maggs pointed out that the Department of Justice was presenting to a special grand jury in Washington a charge that the American Medical Association was engaged in "an alleged conspiracy by organized medicine to suppress, through coercive measures, a new social invention—group medical practice coupled with risk-sharing prepayment of the costs of medical care—a new social invention for which the claim is made that it enables the lower income group to get more and better medical care than it is now getting." His speech was an astute bit of special pleading on behalf of Group Health Association, Inc., and an attack on the American Medical Association and organized medicine, permeated with egregious misstatements of facts. Mr Maggs stated, for instance, that the Medical Society—

"charged that the \$40,000 HOLC grant was an illegal expenditure of government funds. But, on advice of the Legislative Counsel, it was determined in Congress that the grant was wholly proper."

As a matter of fact, Congress never acted on this matter, legislative counsel for the House of Representatives, so far as is known, had nothing to do with it, legislative counsel for the Senate, according to best available information, said only that it was not clear that the Home Owners' Loan Corporation did not have authority to make the expenditure, and then pointed out two ways through which such expenditures might be made clearly illegal in the future, and the chairman of the subcommittee of the House of Representatives' Committee on Appropriations that had charge of the appropriation bill covering monies for Home Owners' Loan Corporation, after an extended hearing, condemned in vigorous language the policy by which representatives of the Corporation undertook to justify the grant.

This statement fairly represents, it is believed, the degree of accuracy with which the special assistant to the Attorney General presented his case to his Milwaukee audience and in which the Department of Justice, through its issue of press releases, presented it to the reading public in Washington and elsewhere.

On December 9 the Medical Society of the District of Columbia filed a motion to instruct the Additional Grand Jury on the law applicable to the matters under consideration by it, with particular reference to the act generally known as the Sherman Antitrust Act. This motion was resisted by the representatives of the Department of Justice having in charge the presentation of the alleged violation of that act by the American Medical Association, the Medical Society of the District of Columbia and others. Thereafter, the court denied the motion. This left the grand jury to act only on such general instructions as to the law as had been given it by the court when it was impaneled and such further instructions as might be given it by representatives of the Department of Justice having the matter of prosecution in charge.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

### CALIFORNIA

**Dr Gibbons in Charge of Exposition Hospital**—Dr Morton R. Gibbons Sr., San Francisco, has been appointed in charge of the hospital to be operated on Treasure Island during the Golden Gate Exposition. The hospital already completed, is housed in the north wing of the Administration Building. After the exposition closes, the hospital will be maintained as a permanent adjunct of the airport. Dr Gibbons was president of the California Medical Association, 1929-1930.

**Society News**—At a joint meeting of the Los Angeles Society of Ophthalmology and Otolaryngology and the Research Study Club of Los Angeles December 19 Dr Samuel Rodman Irvine spoke on 'Present Status of Experimental Cataract and Possible Clinical Significance'. The Los Angeles County Medical Association was addressed December 1 by Drs Emil Bogen on 'Predictability of Routine Laboratory Tests', Ernest M. Hall 'Subacute Alcoholic Cirrhosis' and Newton G. Evans, 'Lutemic Cirrhosis'.

### DISTRICT OF COLUMBIA

**Society News**—Dr William J. Mallory was elected president of the Washington Social Hygiene Society October 12 filling the unexpired term of Dr Earl Baldwin McKinley, who disappeared with the *Hawaiian Clipper* last summer. Dr Mallory is also president of the Medical Society of the District of Columbia. Dr Frank E. Adair, New York, discussed 'Cancer of the Breast' at George Washington University Medical School October 15. A symposium on therapeutics was presented before the Medical Society of the District of Columbia November 30 by Drs Alexander Simon on 'Insulin Treatment of the Psychoses', Walter Freeman and Hyman D. Shapiro, 'Metrazol Treatment of the Neuroses', and Arthur Camp Stanley, 'Observations on the Use of Chaulmoogra Oil in Arthritis'. A symposium on practical considerations of common problems in obstetrics and gynecology was presented before the society December 14 by Drs Lawrence Lee Cockerill, Bernard Notes and James R. Costello. The program was furnished by the Georgetown Clinical Society and the Georgetown University Medical Society.

**Dr Guthrie Joins Staff at St Elizabeths**—The superintendent of St Elizabeths Hospital, Washington, D. C., announced December 23 the appointment of Dr Riley H. Guthrie, Boston, as first assistant physician at the hospital. According to the *Washington Evening Star*, the appointment was based on a civil service examination in which Dr Guthrie received the highest rating. Dr Guthrie is a native of Arkansas and was educated at the University of Arkansas and at the University of Tennessee School of Medicine, Memphis, where he graduated in 1921. He was on the staff of the State Hospital at Little Rock for three years, was in private practice for two years, and then resumed institutional work at the State Hospital at Massillon, Ohio. For six years he was assistant superintendent of the Monson State Hospital at Palmer, Mass. He was appointed assistant to the Massachusetts state commissioner of mental diseases in June 1935 and in the same year became medical officer at the Boston Psychopathic Hospital. Dr Guthrie will assume his new duties at St Elizabeths about January 15. He will be assistant to Dr Winfred Overholser, superintendent, who has been without an assistant since Dr Herbert C. Woolley's resignation nearly two years ago.

### FLORIDA

**New Division of Venereal Disease Control**—The Florida State Board of Health has created a new division of venereal disease control. Dr Leo C. Gonzalez, Jacksonville, head of the Franklin Gulf counties health department, has been appointed director of the new unit and Dr William A. Chapman, Miami, has been named medical consultant for the division's work among the colored people.

**Society News**—Dr Ammon Buist Litterer, Miami, discussed "The Clinical Value of Quantitative Blood Studies in the Management of Syphilis, Including Fever Therapy" before the Dade County Medical Society November 1. The Duval County Medical Society was addressed November 1 by Drs

John F. Lovejoy on "Diagnosis of Pain in the Hip in Children", Shirlar A. Richardson, "Retinal Detachment," and James L. Borland, "The Dysentery Problem in the Jacksonville Area". At a recent meeting of the Leon-Gadsden Liberty-Wakulla Jefferson County Medical Society in Quincy, Drs Rudolph Bell, Thomasville, Ga., spoke on "When to Operate for Urinary Calculi", James C. Robertson, Chattahoochee, "A Review of Syphilis at State Hospital," and Robert F. Godard, Quincy, "Menace of State Medicine".

**Special Society Meetings**—Dr Frederick J. Waas, Jacksonville, was elected president of the Florida East Coast Medical Association at its eleventh annual meeting in Rockledge, October 26-29. Dr Thomas C. Keniston, Cocoa, retiring secretary, was elected vice president and Dr Arthur J. Logie, Jacksonville, was chosen secretary-treasurer. The next annual session will be held in Jacksonville. The association includes all the eastern counties from Fernandina to Key West. The Florida Public Health Association held its tenth annual convention in Hollywood November 28-30. The speakers included Drs Thomas Parran, surgeon general U. S. Public Health Service, Washington, D. C., Stuart I. Kitchen, Tallahassee, John E. Lindendorf Jr., Pensacola, James A. Baker, state health officer, Montgomery, Ala., and James A. Hayne, state health officer, Columbia, S. C.

### ILLINOIS

**Memorial to Physician**—A new \$300,000 diagnostic center was dedicated at Peoria State Hospital Peoria November 1 and named in honor of the late Dr George A. Zeller, formerly superintendent of the institution. A boulder and tablet were also unveiled as a memorial to Dr Zeller. A. L. Bowen, Springfield, director of the state department of public welfare, presided at the dedicatory ceremonies and Dr George W. Mitchell, Peoria, gave the eulogy. The new diagnostic center has a capacity of 200 beds. Dr Zeller died June 29, 1938.

### Chicago

**Changes in Health Department**—Dr G. Howard Gower, director of the Chicago Urban health service and instructor in bacteriology, University of Illinois, has been appointed chief medical officer of the Chicago board of health, effective sometime in January. The post is a newly created one. Dr Isaac D. Rawlings, chief of the bureau of communicable diseases of the board, has been retired on pension at his own request.

**Building Program at Dunning**—An expansion program will begin during 1939 at Dunning State Hospital to include a \$110,000 addition to the main building, a \$375,000 building for a diagnostic center, and a \$200,000 infirmary building. The hospital's normal capacity is 4,000, newspapers reported December 9 that it had 4,200 patients as compared with 478 at the same time in 1937. During the last year 380 patients have been transferred to the new state hospital at Mankato.

### LOUISIANA

**Graduate Assembly**—The third New Orleans Graduate Medical Assembly will be held February 6-9 with eighteen guest speakers providing the program. A preliminary program mentions the following:

Dr Harry J. Shields, Toronto: A Consideration of Anesthetic Procedures in a Large Canadian Hospital and Spinal Anesthesia Practiced in the Toronto General Hospital.  
Dr William P. Wherry, Omaha: Deafness and Mandibular Joint Disorders.  
Dr Frederick T. Tisdall, Toronto: Role of Nutrition in the Care of Your Patient and Prevention and Cure of Vitamin and Mineral Deficiencies.  
Dr Wiley D. Forbus, Durham, N. C.: Variations in Morphology of Reaction to Injury Considered in Relation to the Determining Factors and the Clinical and Pathological Aspects of Chronic Pyelonephritis.  
Dr Cyrus C. Sturgis, Ann Arbor: The Menace and Treatment of Obesity and Treatment of the Anemia of Pregnancy.

### MARYLAND

**The DeLamar Lectures**—According to the Johns Hopkins University School of Hygiene and Public Health, Baltimore, the following DeLamar lectures make up the series for the present session:

Rupert B. Vance, Ph.D., Chapel Hill: November 1: Social and Economic Problems of the Rural South.  
Dr Carl Ten Broeck, Princeton, N. J.: December 6: Encephalomyelitis in Horses.  
Dr Martha M. Eliot, Washington, D. C.: January 10: Child Health.  
Dr George R. Minot, Boston: February 14: Anemia.  
Dr Edward Stuart Russell, director of fishery investigations, Ministry of Agriculture and Fisheries, University College, London: February 15: Populations and the Effect of Fishing. Dr Russell's subject will be covered in five lectures to be given in April although the exact dates have not yet been decided.

## MASSACHUSETTS

**Soma Weiss to Be Physician-in-Chief at Peter Bent Brigham**—Dr. Soma Weiss, associate professor of medicine, Harvard University Medical School, Boston, and assistant director of the Thorndike Memorial Laboratory of Boston City Hospital, has been appointed physician-in-chief of Peter Bent Brigham Hospital to succeed Dr. Henry A. Christian. The appointment will be effective September 1. Dr. Weiss will become professor of medicine at the same time. A native of Besterecz Hungary, Dr. Weiss received the degree of doctor of medicine at Cornell University Medical College in 1923. He taught biochemistry at the Royal Hungarian University from 1918 to 1920, when he became assistant in pharmacology at Cornell. He joined the faculty at Harvard in 1925 as assistant in medicine, subsequently serving in various capacities until 1932, when he was named associate professor of medicine. Dr. Weiss will be the second physician-in-chief at the Peter Bent Brigham Hospital, Dr. Christian having served since the hospital was completed in 1912.

**Appointments in Department of Mental Health**—Dr. Francis H. Sleeper, assistant superintendent of the Worcester State Hospital, has been appointed to the newly established position of director of hospital inspection for the department of mental health, it is announced. The appointment of Dr. Birdwell H. Flower, assistant superintendent of the Grafton State Hospital, as assistant commissioner in the state department of mental health has been approved by the executive council, according to the Boston *Herald*. Dr. William C. Gaebler, assistant superintendent of the Foxboro State Hospital, has also been appointed an assistant in the department, according to the *Herald*. He will make special investigations and coordinate the medical and business affairs of the various state hospitals. Dr. Edgar C. Yerbury, assistant superintendent of the Danvers State Hospital, has been appointed director of the division of mental hygiene in the state department of mental health, newspapers reported. Dr. Yerbury graduated at the Boston University School of Medicine in 1921. Dr. Ella P. Cahill, Cambridge, has been appointed senior psychiatrist in the division, succeeding Dr. Olive A. Cooper, Revere, who has been named director of the Springfield Child Guidance Clinic, sponsored jointly by the department of mental health and the Springfield Community Chest.

## MICHIGAN

**Personal**—Stanislas M. Keenan, Detroit, historian of Eloise Hospital, died December 6. He was an honorary member of the Detroit Roentgen Ray and Radium Society and member of the American Roentgen Ray Society.—Dr. Leverett S. Woodworth, New York, has been appointed assistant director of Harper Hospital, Detroit.

**Society News**—Dr. Joseph C. Birdsall, Philadelphia, addressed the Wayne County Medical Society December 19 under the auspices of the Detroit branch of the American Urological Association, his subject was "Renal Pathology and Its Correction in Urinary Tract Obstructions".—Dr. Fenimore E. Davis, Ann Arbor, discussed "Recent Advances in Anesthesia and Analgesia" before the Genesee County Medical Society November 30.

**New University Hospital**—The new university hospital now under construction at the Michigan State College has been named in honor of the late Dr. Richard M. Olin, East Lansing, who from 1925 had been director of the college health service. A graduate of University and Bellevue Hospital Medical College in 1899, Dr. Olin entered practice in Caro the same year. He served as head of the sanitary department of the St. Louis Exposition. In 1917 he became secretary of the state board of health in Lansing and in 1919 was appointed the first state health commissioner, a post created under a reorganization of the department. Dr. Charles F. Holland, assistant physician to the college health service, has been appointed acting head of the health service, effective to the end of the current fiscal year.

## MISSISSIPPI

**Public Health Meeting**—Dr. William H. Cleveland, Tupelo health officer of Lee County, was chosen president-elect of the Mississippi Public Health Association at its third annual session in Jackson December 9. Dr. Francis Michael Smith, Vicksburg health officer of Warren County, was inducted into the presidency, succeeding H. A. Kroeze, state director of sanitation. Dr. John A. Milne Jackson, director of county health work, state department of health, was reelected

secretary. The speakers included Abel Wolman, Baltimore, on "Housing in Its Relation to Public Health" and Dr. Henry C. Ricks, Jackson, procedures in typing pneumonia.

**Plan to Augment Medical Library**—Three thousand volumes of miscellaneous medical and surgical works have been added to the Rowland Medical Library of the University of Mississippi during the past year, the first in a five year program to enlarge the library. In January the board of trustees voted to name the medical library in honor of Dr. Peter W. Rowland, professor of pharmacology at the school, in recognition of his voluntary services in securing books for the library. According to the first annual report, in addition to the acquisition of 3,000 volumes, contributions of \$2,500 from medical alumni were received to purchase new books. A reprint file was also begun during the year. According to the report, a special appropriation of \$3,000 in 1936 provided for new quarters including a reading room, two study rooms and the librarian's office. In the spring of 1937 Dr. Rowland volunteered his services and became field director of the library. It is hoped that in the remaining four years of the program a valuable collection will be assembled for the medical students and physicians in the state.

## NEW JERSEY

**Committee Studies Eugenic Sterilization**—A special committee of the Medical Society of New Jersey organized for the study of eugenic sterilization recently outlined its objectives in the state medical journal. The committee plans to accumulate information concerning the surgical and eugenic aspects of sterilization and to distribute information to the medical profession. It wishes to become familiar with the work of lay organizations interested in the subject, to make known their conclusions to the medical profession and to cooperate with them by giving them the benefit of medical experience and by helping them to follow scientific medical principles. Finally it wishes to make available competent surgical service for those who need and desire such operations. The committee plans to collect data on operations and indications for sterilization and make it available through the package library of the state medical society. The names of surgeons and hospitals available for such operations will be sought and will be given to persons desiring this service.

## NEW YORK

**Society News**—Drs. John B. Alsever and Charles A. Gwynn addressed the Syracuse Academy of Medicine December 20 on "Collection and Preservation of Placental Blood for Transfusion Purposes".—Dr. William S. McCann, Rochester, addressed the Oswego County Medical Society November 23 on "Practical Consideration of Water in the Body".—The program of the Medical Society of the County of Nassau November 29 was presented by the Nassau County Surgical Society with the following speakers: Drs. Arthur C. Martin, on "Causes of Nonobstetrical Vaginal Bleeding", Otho C. Hudson, "Emergency Treatment of Fractures", Richard Derby, Oyster Bay, "Causes of Rectal Bleeding", and Algernon S. Warinner, "A Lump in the Breast". The surgical society was recently organized with Dr. Benjamin W. Seaman, Hempstead, as president and Dr. Hudson as secretary.—Dr. Richard E. Shope, Princeton, N. J., addressed the Rochester Academy of Medicine December 8 on "Recent Advances in Our Knowledge of the Virus Diseases".—Dr. John S. Lawrence, Rochester, addressed the Glens Falls Academy of Medicine November 22 on "Agranulocytosis—Human and Experimental".

## New York City

**World's Fair Pharmacy Building Dedicated**—The Hall of Pharmacy at the New York World's Fair was dedicated November 13. Mary Pickford raised the American flag above the building and the speakers included Deputy Mayor Henry H. Curran, James L. Fieser, vice chairman of the American Red Cross, Washington, D. C., William Jay Schieffelin, chairman of the dedication committee, Grover A. Whalen, president of the fair, and Joseph A. Huisking, chairman of the committee for the drug industry's participation in the fair.

**Course in Neuro-Ophthalmology**—Mount Sinai Hospital in cooperation with Columbia University offers an eight weeks course in neuro-ophthalmology, February 6 to March 31, under Drs. Morris B. Bender and Nathan Savitsky. It will consist of the anatomy and physiology of the motor and sensory systems of the eye and of clinical and experimental demonstrations. It will be given for a minimum of four students. Apply to the Secretary for Medical Instruction Mount Sinai Hospital, Fifth Avenue and One Hundredth Street.

**Opening in Bureau of Child Guidance**—The board of education of New York City has announced an examination for a license as assistant medical director of the bureau of child guidance. The salary is \$10,000 a year. The position involves the supervision of child guidance clinic units situated in various parts of the city. Applicants must not be over 46 years of age, must be graduates of an approved medical school and must have had twelve semester hours in approved and appropriate courses in psychiatry and psychology and eight semester hours in approved courses in supervision and in administration or organization. The latter requirement of eight semester hours may be completed within three years after appointment. Applicants must have five years of practice in psychiatry, including 800 hours of appropriate clinical experience in institutions for treatment of mental disease and 1,200 hours of appropriate experience in approved clinics for the study and treatment of personality and behavior disorders of children and three years of experience as a psychiatrist in a child guidance clinic in a school system or in supervision in an approved clinic for the study and treatment of personality and behavior disorders of children. Application in complete form must be postmarked no later than January 15. Complete information may be obtained from the board of education, 500 Park Avenue.

## OHIO

**District Meetings**—At the semiannual meeting of the Union District Medical Association, Hamilton, October 27, the speakers were Drs. Elroy T. Storer, Middletown, on "As Laymen See Us," Parke G. Smith, Cincinnati, "Abnormal Renal Mobility," Max M. Zimmerer, Cincinnati, "Treatment of Stomach and Duodenal Lesions," and John R. Pate, Louisville, Ky., "Certain Aspects of the Control of Syphilis."—Guest speakers at a meeting of the Eighth District of the Ohio State Medical Association at Granville, October 27, were Drs. Norman R. Kretzschmar, Ann Arbor, on "Surgical Treatment of Pelvic Abscess and Cellulitis," and Endocrinology in Gynecologic Practice," Fred J. Hodges, Ann Arbor, "X-Ray Diagnosis of Gastrointestinal Disease," and George H. Gardner, Chicago, "Frequently Encountered Lesions of the Cervix Uteri."

**Dr. Corrigan Named Ambassador to Venezuela**—Dr. Francis P. Corrigan, Cleveland, and now minister to Panama, has been appointed by President Roosevelt as the first United States ambassador to Venezuela, according to the *Cleveland Plain Dealer*. A native of Cleveland, Dr. Corrigan graduated at Western Reserve University School of Medicine in 1906. He completed his internship at St. Alexis Hospital, later serving as pathologist and from 1910 to 1917 as surgeon. He was chief surgeon of the Chile Exploration Hospital 1917-1919. Subsequently he engaged in organization work in South America for the American College of Surgeons. From 1922 to 1932 he was concurrently consulting surgeon to St. John's Hospital and director of surgery at St. Alexis. He has served as envoy extraordinary and minister plenipotentiary to San Salvador since 1934. He was special representative of the President of the United States in 1935 at the inauguration of President Martinez of El Salvador and since 1937 has been envoy extraordinary and minister plenipotentiary to Panama. He was representative of the United States of America in the Mediation Commission in the boundary controversy between Nicaragua and Honduras, San Jose, Costa Rica, November-December 1937. Dr. Corrigan is also the author of several books.

## PENNSYLVANIA

**Hospital News**—A new building providing more than 300 beds was dedicated at the Norristown State Hospital, Norristown, October 20. Two old buildings were recently renovated as part of a program for which the legislature has appropriated \$2,000,000.

## Philadelphia

**Personal**—Clarence Marshall, D.V.M., professor of veterinary medicine at the University of Pennsylvania, died October 29, aged 74. He was a former president of the American Veterinary Medical Association and was a member of the advisory council of the state board of health.—Dr. Herbert M. Goddard has been appointed assistant director of public health to succeed the late Dr. Alfred F. Allman.

**Society News**—Drs. Norton Canfield, New Haven, Conn., and Julius Lempert, New York, addressed a joint meeting of the Philadelphia Laryngological Society and the section on otolaryngology of the College of Physicians of Philadelphia

December 13 on "Labyrinthine Fistulas" and "Experience with Surgical Penetration of the External Semicircular Canal: Improvement of Hearing in Otosclerosis" respectively.—Dr. Arnold L. Gesell, New Haven, Conn., addressed the Philadelphia Pediatric Society December 13 on "The Place of Developmental Diagnosis in Clinical Pediatrics."—At a meeting of the Pennsylvania State Physical Therapy Association December 15 the speakers were Drs. Oscar T. Wood Jr. and William H. Schmidt on "Treatment of Chorea by Artificial Fever" and "Treatment of Strick Syndrome" respectively.—Dr. Eric Miles Atkinson, New York, among others, addressed the Philadelphia Neurological Society December 16 on "Localized Nonsuppurative Encephalitis as a Clinical Entity."—Dr. Elliott P. Joslin, Boston, was the guest speaker at a meeting of the Philadelphia County Medical Society December 18 on "Changing Aspects of Diabetes." Miss Catherine Roe, representing the Philadelphia Dietetic Association, spoke on "Interpretation of Diabetic Diet Prescriptions" and Dr. Joseph F. Beardwood Jr., representing the Philadelphia Metabolic Association, discussed metabolism.—Dr. William Bord, Toronto, addressed the College of Physicians of Philadelphia December 7 in the fifty-first Thomas Dent Mütter Lecture on "Some Reasons for the Recent Increase in Bronchial Carcinoma."

## UTAH

**Program on Pneumonia Control**—The Utah State Board of Health recently sponsored a program on the management of pneumonia preliminary to opening a campaign to control the disease throughout the state. The program included the showing of a film on the recent developments in pneumonia management and lectures by Dr. George F. Cooper, San Francisco, a technical medical adviser on pneumonia management. Meetings were arranged in every section of the state through the cooperation of the component medical societies with the deputy state district health officers.

## WISCONSIN

**Personal**—Dr. Mary Allen, Cleveland, was recently appointed staff physician of the bureau of maternal and child health of the state department of health. She succeeds Dr. Ruth A. B. Bennett, Galveston, Texas, who resigned.—Dr. Albert F. Young will retire as superintendent of the Milwaukee Hospital for Mental Diseases, Wauwatosa, January 1. Dr. Young was appointed first assistant at the hospital in 1894 and superintendent in 1916.

**Society News**—A symposium on orthopedic subjects was presented before the Medical Society of Milwaukee County November 11 by the following physicians: Drs. David J. Ansfield, on faulty posture in childhood, Harry B. Sadoff, handling of the injured, John O. Dieterle, diagnosis of spinal injuries, and Albert C. Schmidt, diagnosis and treatment of fractures of the ankle.—A symposium on tumors of the bladder was presented at a meeting of the Wood County Medical Society, Wisconsin Rapids, November 3, by Drs. Walter G. Sexton, Robert S. Baldwin, Roy P. Potter and Stephan Epstein, Marshfield. Drs. Donald Waters and Rogers E. Garrison, Wisconsin Rapids, spoke on "Multiple Myeloma" and "Melanosarcoma" respectively.—Dr. Julius L. Spivack, Chicago, addressed the Milwaukee Society of Clinical Surgery November 22 on "Some Points in the Technic of Appendectomy" and Dr. Silvanus A. Morton, Milwaukee, on "Relation of Surgery and Radiation Therapy in the Treatment of Cancer."

## GENERAL

**Medical Missions to Be Coordinated**—The Christian Medical Council for Overseas Work was recently formed in New York to represent twelve foreign mission boards active in medical work. Dr. Edward H. Hume, who has spent many years in medical work in China, will be director of the new council, which will have its headquarters at 156 Fifth Avenue, New York. The new organization will act as an advisory body and will aid in development of facilities at home for training and retraining doctors and nurses for overseas service.

**Otolaryngology Examinations**—One hundred and twenty-nine candidates were examined by the American Board of Otolaryngology in Washington, D. C., October 7-8. Ninety-seven were certificated. During 1939 examinations will be held in St. Louis May 12-13 prior to the annual session of the American Medical Association and in Chicago October 6-7 before the meeting of the American Academy of Ophthalmology and Oto-

**Laryngology** Prospective applicants for certificates should secure application blanks from the secretary, Dr William P Wherry, 1500 Medical Arts Building, Omaha, Neb

**Check Forger Is Swindling Physicians**—From Virginia comes a report of a man who has recently visited eye, ear, nose and throat specialists, usually for an eye examination, and has then presented forged checks for more than his bill, receiving considerable amounts in change. He poses as a farmer and the check he presents, which is made out to him, is marked "For 1 Holstein heifer." The checks are signed with names of prominent persons in other towns than the one in which he is operating. He is described as being about 48 years old and weighing about 165 pounds, with sandy hair and brown eyes.

**Society Elections**—Dr Julian L Rawls, Norfolk, was elected president of the Seaboard Medical Association at the annual meeting in Greenville, N C, December 6-8. The following vice presidents were elected: Drs William M B Brown, Greenville; John L Rawls, Suffolk, Va; John A Payne, Sunbury, N C, and Southgate Leigh Jr, Norfolk. Dr Clarence Porter Jones Sr, Newport News, Va, was reelected secretary. Dr Brinn C Svord, New Haven, Conn, was elected president of the American Society of Anesthetists at its annual meeting in Philadelphia December 8. Dr Fayette Elmore Hubbard, Montclair, N J, was elected vice president and Dr Paul M Wood, New York, reelected secretary. The society will hold four stated meetings during the year in New York and two meetings in other cities.

**World Sclerosis Conference**—The International Labor Office at Geneva, Switzerland, conducted a sclerosis conference from August 29 to September 10. Drs Royd R Sayers, senior surgeon division of industrial hygiene, U S Public Health Service, Washington, D C, Leroy U Gardner, director, Saranac Laboratory for Study of Tuberculosis Saranac Lake N Y, and Leonard Greenburg, executive director, division of industrial hygiene, New York State Department of Labor, New York, represented the United States. Other countries represented were Australia, Belgium, France, Great Britain, Japan, Denmark, Switzerland, the Netherlands and the Union of South Africa. The report of the conference dealt with definitions and diagnosis of sclerosis and included suggestions for preventing it. It recommended the use of dust protection masks only when the suppression of the dust at its source is impossible.

**Statement by Trustee of McKesson & Robbins**—William J Wardall, sole trustee of McKesson & Robbins, issued a statement December 24 indicating that the company is carrying on its regular business of manufacturing and distributing drugs. Mr Wardall said "While the fictitious operations of Coster and his group in crude drugs were carried out in terms of equally fictitious warehouses and companies, the real business of McKesson & Robbins in manufacturing drugs and other preparations in accordance with the rigid standards of the Food and Drug Act and in wholesaling the equally high grade products of other manufacturers, is continuing." The statement added that manufacturers are continuing to distribute their products through the firm and retail druggists are continuing to buy these products from the company. The statement concluded "In the meantime, I am continuing the intensive investigation into the financial affairs of the company in cooperation with all other agencies and expect to have something further to say on the subject as soon as my investigation has reached the point where essential facts can be determined."

**Health Record in the United States for 1938**—No previous year has even closely approached the record of the United States for low mortality established for 1938, according to Louis I Dublin, Ph D, statistician of the Metropolitan Life Insurance Company, New York. Month after month the death rates among the many millions of persons who were industrial policy holders of this company have been even lower than during 1937. In the middle of December the year-to-date death rate was more than 7 per cent below the previous minimum established in 1937. Information for the first nine months of 1938 was available also from the health officers of thirty-nine states, and their story, without exception, shows an improved mortality rate in 1938 as compared with 1937. It is practically certain, Dr Dublin says, that 1938 will be acclaimed the banner health year in the history of the United States.

The death rates from tuberculosis pneumonia and influenza have reached new minima for the United States during 1938. It is almost certain that the mortality from tuberculosis for the country as a whole will drop below 50 per 100,000, for the first time in history. If the present rate of decline con-

tinues for a few more years tuberculosis will reach the stage at which the number of open cases will no longer be sufficient to maintain it among the leading causes of death in this country.

There were no major epidemics of influenza or pneumonia in 1938. In the case of pneumonia, there was also the added factor, no doubt, of the wide adoption of the new serum treatment against the more prevalent types of pneumococcus. The sole exception to this rule, in 1938, was the continuance of the rise in deaths charged to coronary artery disease. But this increase may be only apparent, reflecting improved diagnosis together with the newly awakened interest of physicians in this form of heart disease.

Among the most gratifying aspects of the mortality picture for 1938 was the marked decline in automobile fatalities. Present figures indicate that the final tabulation will show fewer deaths by one fifth from this cause than were recorded in 1937 and this will mean about 8,000 lives saved. Fatal occupational accidents, as well as those occurring in public places, likewise resulted in fewer fatalities this year, although accidents in the home appear to have been as numerous as those reported a year ago.

Further gains against both infant and maternal mortality also contributed to the salutary state of public health during the past year. It is safe to report new minimal death rates in both of these important fields of public health work.

Aside from the rise in mortality from coronary artery disease, about the only disturbing feature of the present mortality picture is the continued increase of the cancer death rate. The year 1938 is the twentieth consecutive year to register a rise in this malignant form of human affliction. There is some doubt, however, as to whether this upward trend in cancer deaths actually marks an increase of the disease or merely reflects the rapid aging of our population. Improved means of diagnosis and more accurate reporting also have been important elements in the apparent increase in cancer mortality.

All but two of the leading communicable diseases showed below-normal prevalence during 1938. The country was especially blessed in that it was comparatively free from poliomyelitis (infantile paralysis). Less than 1,700 cases were recorded throughout the entire country and no section has suffered what might be called a major outbreak.

Only measles and smallpox were unusually prevalent during the current year. Fortunately neither of them was responsible for much mortality, although the exceptionally low death rate from measles in 1937 was probably quadrupled in 1938.

**Section Meetings of Otolaryngologists**—The annual section meetings of the American Laryngological, Rhinological and Otolological Society will be held during January in Boston, New Orleans, Sioux City, Iowa, and Spokane, Wash. The eastern meeting will be in conjunction with the New England Otolaryngological Society at the Massachusetts Eye and Ear Infirmary, Boston, January 29. The speakers will include:

- Dr Westley M Hunt New York Esophageal Abscess—the Importance of Early Intervention
- Dr De Forest C Jarvis Barre Vt Twelve Varieties of the Common Cold
- Dr William Mithoefer Cincinnati Pertinent Facts Concerning Pan-sinusitis

The southern section will meet at the Roosevelt Hotel, New Orleans, January 14, with the following speakers, among others:

- Dr Watt W Eagle Durham N C Nasopharyngeal Cysts (Thornwaldt's Bursa)
- Dr Harvey B Searcy Tuscaloosa Ala Oily Solutions for Sinus Irrigation
- Dr James W Jervy Greenville S C Insulin and Other Therapy in Otolaryngology A Comparative Study
- Dr Robert G Reaves Knoxville Tenn Motion Pictures of Intranasal Sinus Operation with Animated Illustrations

The middle section will meet January 19-20 with the Sioux Valley Eye and Ear Academy at Sioux City. The speakers will include:

- Dr Allen C Starry Sioux City Iowa Pathology of the Tonsil
- Dr Horace Newhart Minneapolis A State Program for the Conservation of Hearing
- Dr Millard F Arbuckle St Louis The Bronchoscopist in the Thoracic Surgery Team
- Dr Howard C Ballenger Chicago Osteomyelitis of the Sphenoid

The western meeting will be at the Davenport Hotel, Spokane, Wash, January 29. Among the speakers will be:

- Dr Aubrey G Rawlins San Francisco Operative Procedure for the Relief of Stenosis in Double Abductor Paralysis of the Larynx
- Dr Brien T King Seattle A New and Function Restoring Operation for Bilateral Recurrent Nerve Paralysis
- Drs Edwin J Barnett and Harold D Carnahan Spokane Nasal Allergy in Children
- Dr Ralph A Fenton Portland Ore The Present Status of Sulfanilamide in Otolaryngology

#### Radium Beam Therapy

The Medical Research Council has issued a report on radium beam therapy which is the outcome of work done under an organization known as the Radium Beam Therapy Research, consisting of leaders of the medical profession and eminent physicists such as the late Lord Rutherford. Physical research preceded clinical work, so that everything was done to protect patients and staff. The investigation extended over four years, during which 366 patients were treated. There was no case of the slightest damage from radiation either to patients or to staff. The radium used was a unit of 5 Gm, which was subsequently increased to 10 Gm. The greatest care had to be taken in moving such a large amount. A pneumatic transference device enabled the radium to be taken from the safe where it was kept and to be placed in the required position without any handling by or exposure of the operators. The exact placing of the patient and the adjustment of the apparatus were done before the radium was in working position. Thus the necessary care and time could be given to the preliminary adjustments, as all danger of manipulation was avoided. The apparatus was a modification of that designed by Sievert of Stockholm which secures the maximum protection for patient and staff. Difficulties encountered were the lack of a standard unit of dosage and of a method of directing the radiation accurately and estimating the amount received at the site of the disease and in the body generally. These were largely overcome. The beam was directed by a directional caliper, and the radiation received by the tissues was calculated from specially prepared charts. Total radiation was estimated by an "electrical condenser in the form of a man." The general effects of radiation were estimated by regular blood counts, the most important effect being a diminution of the total leukocytes. No one except the patient was present in the treatment room during the whole course of the exposure, but communication between nurse and patient was rendered easy by an ingenious installation of microphones and loud speakers, while observation was conducted by a system of periscopic mirrors.

It was decided to limit the investigation to cancers of the mouth, tongue, larynx and pharynx, which are easily accessible to inspection and treatment and for which operations have to be drastic and often ultimately fail. Good results have been obtained by the interstitial insertion of small radium needles, but this means surgical intervention and much discomfort when the needles are in position. Beam therapy is conducted externally as with x-rays and the discomfort of needles is avoided, although a certain amount of discomfort is inevitable. Reaction of skin and mucous membrane is bound to occur, but the patient is much more comfortable than after interstitial irradiation and incomparably more so than after the mutilations of surgical treatment.

#### RESULTS

Complete disappearance of early and localized growths may be expected. When lymphatic glands in close proximity are involved, their enlargement may be made to disappear. Even with advanced primary growth and local lymphatic involvement, disappearance may occur in a small proportion of cases and many distressing symptoms be relieved in a large proportion. Though it is too early for definite pronouncement, the treatment by radium beam is at least as satisfactory as surgical intervention or interstitial application of radium. Fur-

ther work with a 10 Gm unit is to be undertaken on cancer of the breast. Of the 366 patients treated from 1934 to 1937, forty-four died of intercurrent disease. Of the remaining 322, only thirty-four had operable growths. Of these, 122, or 37.8 per cent, were symptomless in January 1938. Of the patients treated in 1934, 32 per cent were symptom free after three years. The curability rate of cancer of the tongue, floor of the mouth, alveolus and palate is similar to that for other methods, but cancer of the tonsil, pharynx, larynx and post-cricoid region shows a decided balance in favor of beam therapy. No less than 102 patients with cancer of the pharynx were treated and thirty-three were rendered symptom free. In the treatment of inoperable cervical lymph glands, other methods have proved of little value. In seven cases palpable masses or infiltrations disappeared under beam therapy and the patient remained symptom free for from eighteen months to three years.

#### Every Hospital in British Empire to Have a Respirator

The munificent gifts to medicine by Lord Nuffield the automobile magnate, have been reported previously. The latest is the presentation to every hospital in the British Empire of a respirator of the 'iron lung' type, known as the Both respirator. Owing to their high cost and the infrequency with which they are required only a few hospitals have respirators, and when an emergency arises one has to be borrowed, with delay and difficulty which may mean loss of life. Lord Nuffield will manufacture the respirators at a probable cost of \$500 each. It is estimated that there will be a demand for 5,000, so that his gift will amount to \$2,500,000. His interest in 'the iron lung' was stimulated by a film on artificial respiration prepared by the department of anaesthetics of the University of Oxford, to which he has made colossal gifts for the development of the medical school. The respirator which Lord Nuffield is making is designed by the young Australian inventor Mr. E. T. Both and owes its creation to the severe epidemic of infantile paralysis which prevailed in Australia in 1937, in which it was used with success. After all applications for respirators have been complied with, stocks will be kept in readiness for any sudden epidemic. Unlike its predecessors the Both respirator is made of laminated wood. It is operated by a half-horse power motor where electricity is available and otherwise by hand.

#### Tenth French Pediatric Congress

The subjects chosen for special reports and general discussion during the 1938 session of the French Pediatric Congress were (1) severe anemias in infancy, (2) the malignant syndrome in the course of the acute infectious diseases and (3) megacolon and dolichocolon.

#### SEVERE ANEMIAS IN INFANCY

Dr. Louise Weill gave as normal figures for the blood in infancy erythrocytes 4,200,000, hemoglobin 75 to 85 per cent and leukocytes 6,000 to 12,000 with a predominance of mononuclears. The instability of the hemopoietic organs is a striking characteristic of the blood in infancy, revealing itself in the frequent appearance of immature cells such as erythroblasts or nucleated red corpuscles and of myelocytes. The presence of these two pathologic forms is of less importance in the blood of infants than in that of adults. There are two types of pernicious anemia, the plastic and the aplastic. The latter is rarely observed in infants. On the other hand, pseudoleukemic, or splenic, anemia in infants is the most common type. In addition to the marked decrease in the number of red corpuscles, it is especially characterized by splenomegaly, intense erythroblas-

tosis and a marked reaction of the red bone marrow. There is also extreme pallor, but there are no hemorrhages and only slight hepatomegaly. Examination of the blood reveals a decrease in the number of red corpuscles, the hemoglobin content and the color index, slight lymphocytosis and the presence of megakaryoblasts. This splenic type of anemia is not always fatal, and recovery may take place if the cause is eliminated. It must be differentiated from leukemia, from which recovery is extremely rare. Clinically, all types of splenic anemia are encountered, from benign to very severe. Differentiation from leukemia depends on the course and the number of lymphocytes. The results of sternal puncture may often be of great aid. In the etiology, syphilis plays an important part. In general, the health of the mother during pregnancy is of great influence, because all the anemias observed in infancy are of congenital origin. Treatment includes the administration of vitamins, anti-syphilitic medication, medullary opotherapy, hemotherapy and, in some cases, splenectomy.

#### MALIGNANT (TOXIC) SYNDROME IN THE ACUTE INFECTIOUS DISEASES

Dr R. A. Marquely and Miss Ladet of Paris based their report on the observation of sixty-two cases. The syndrome is characterized by (a) symptoms of nervous origin such as adynamia, asthenia or ataxia and convulsions, (b) hyperthermia, (c) cardiovascular and respiratory (dyspnea) disturbance and (d) digestive and renal symptoms, hemorrhages and erythema. At necropsy one finds generalized hyperemia, submucous hemorrhages in the digestive tract and tumefaction of lymphoid tissue. As to the cause, the most plausible theory is that the condition is the result of some dysfunction of the autonomic nervous system. Reilly and his co-workers reported their experimental work in 1935. They found that the hemorrhages and the vascular and lymphatic lesions could be reproduced by injecting various bacterial toxins into the perisplanchic tissues. The lesions do not present any specific characteristics depending on the type of toxin which has been injected. They are found even after injection of mineral poisons such as lead or nickel, arsenic and even nicotine. In closing, the authors of the report expressed the hope that some preparation would be found which, by acting directly on the sympathetic nervous system, could be used at the onset of any acute infectious disease to prevent the development of the malignant syndrome.

In the discussion of this report, Professor Lereboullet of Paris emphasized the prominence in the clinical picture of adrenal dysfunction, which responds so well to opotherapy. Dr Lesne of Paris called attention to certain associated humoral changes which have an unquestionable prognostic value when accompanied by a high nonprotein nitrogen content of the blood. These changes are a decrease in the cholesterol and in the inorganic phosphorus content of the blood. Professor Cathala of Paris said that a distinction must be made between the malignant (toxic) syndrome in the course of an acute infectious disease and the malignant forms of the disease. Dr Robert Clement and his co-workers reported a case in which the syndrome appeared on the fortieth day of diphtheria. After epinephrine, total epinephrine extract, ouabain and strychnine in large doses had been given, rapid improvement followed the injection of adrenal cortex extract. Dr Grenet of Paris reported cases of spontaneous recovery from a malignant (toxic) syndrome which appeared on the fiftieth day of diphtheria. Dr Ribadeau Dumas of Paris preferred the term "toxic syndrome" to "malignant syndrome." The essential lesions are hyperemia and hemorrhages in the vicinity of the third ventricle. As a rule one can do little in the way of treatment. Dr Caussade of Nancy reported four cases with three deaths, in which the chief symptoms were adynamia, coma and cyanosis. In two of the three fatal cases encephalitis or another infection was found at necropsy. In addition there was marked hyperemia of all the viscera.

#### MEGACOLON AND DOLICHOCOLON

The pathogenesis of megacolon was the subject of the first part of a paper by Prof. Paul Rohmer and Dr. Albert Vallette of the University of Strasbourg pediatric clinic. Recent contributions to our knowledge of dysfunction of the autonomic innervation of the intestine have created renewed interest in megacolon. The most convincing evidence has been furnished by the results of operations on the abdominal sympathetic nerves. The authors collected reports of seventy-one cases, in sixty-one of which the condition had been either completely relieved or at least greatly improved after operation on the sympathetic nerves; four operations gave only partial improvement, two were failures and four patients died. Paessler collected 117 cases of idiopathic megacolon which had been treated by sympathectomy; in eighty-five there was cure or marked improvement, in 12 per cent failure and in 3 per cent death following operation. These results demonstrate the predominant influence of the sympathetic nerves on megacolon (Hirschsprung's disease), because in a large percentage of cases operative elimination of this influence led not only to a clinical cure or marked amelioration but also to a cure from the anatomic standpoint. Adamson and Aird in 1932 showed experimentally that division of the nerves of Eckard (parasympathetic innervation) is followed by typical megacolon and that the colon returns to its normal volume after division of the two lumbar sympathetic nerves. The occasional association of megacolon and megabladder also speaks for hyperfunction of their common sympathetic innervation (hypogastric plexus). Megacolon may now be regarded as due to some abdominal vagosympathetic dysfunction the origin of which is still obscure. It can be due to various peripheral and central causes. Its congenital origin can be explained by the fact that the organism in the fetal and neonatal period in general shows a predisposition to hyper-sympathicotonic states.

The second part of the paper was devoted to dolichocolon. In spite of the resemblance clinically of this condition to megacolon, there is a difference as to both the pathologic process and the pathogenesis. By dolichocolon is meant an abnormal elongation of the colon which should be considered as a congenital malformation. It is observed rarely in infants and children and most commonly in adults. As a rule dolichocolon does not give rise to symptoms in children, but there have been reported cases in which pain and fever predominated the clinical picture resembling that of appendicitis, cases in which vomiting was the dominant symptom, and, finally, cases in which the clinical picture was that of intestinal obstruction. The origin is still obscure. The treatment is medical unless complications occur. The surgical aspects of megacolon and dolichocolon were discussed by Dr. Marcel Boppe of Paris. One can assume as a working hypothesis that either hyperfunction of the sympathetic nerves or hypofunction of the parasympathetic nerves is responsible for megacolon. If the former exists, the most logical procedure would be division of the inhibitory sympathetic fibers to allow the motor action of the parasympathetic nerves to be free to function. If the second hypothesis is true, it is logical to operate on the involuntary sphincters, i. e. to do a sphincterectomy.

The author collected reports of 119 operations on the sympathetic nerves for megacolon, ten of which he himself observed. All the patients were children less than 15 years of age. There were nine operative deaths and seventeen failures. The author's impression was that for older children the mortality is very low after division of the sympathetic fibers. Although the operation has a favorable influence on peristalsis, this is rather uncertain and often only transitory. His conclusion was that it was too early to evaluate the results of operations on the sympathetic nerves in the treatment of megacolon.

In view of the high mortality and complications of one step colectomy, this operation has been discarded by most surgeons.

in favor of segmentary colectomy performed in stages. Only sigmoidectomy or splenic hemicolectomy in three stages are to be retained as feasible procedures.

#### Campaign Against the Misuse of Narcotics

Crime Commissioner W. Thomas, director of the national police antinarcotic center, lectured on the misuse of narcotics before the fifth congress of the European Association of Mental Hygiene at Munich. The national center has its headquarters in the national police headquarters, Berlin. It functions as a clearing house of information for all police problems, German and international, relating to narcotics. The master card index contains some 9,000 cards, more than 2,200 of which represent the records of addicts who are criminals or whose addiction has been discovered in connection with crime. The card index is arranged so as to provide information on addicts according to occupation and according to type of addiction. The center has established throughout the reich fifteen branches known as centers for the collection of information relating to drug addiction. A police net is thus spread over the entire country. Public prosecutors also communicate any pertinent data to the center.

The center keeps abreast of pending proceedings in the criminal courts, provides expert medicolegal testimony and sends its officers to assist local police authorities in difficult cases. It also seeks greater unification of antinarcotic laws.

Besides combating illicit traffic in narcotics the bureau is instrumental in the apprehension of individual addicts who seek to obtain narcotics illegally by forged prescriptions and other fraudulent means. It is a notorious fact that in 1928 there were an estimated 8,000 drug addicts in Germany, so if as mentioned, 2,200 addicts are classified as criminals, every fourth addict has already run afoul of the law and an increase in drug addiction will lead to an increase in crime unless combative measures are instituted.

#### COMMITMENT TO INSTITUTIONS

Accordingly, as Thomas states, further legal restrictions are being carried out by the Nazi government. A criminal narcotic addict can now be committed to a hospital for mental diseases if public safety so demands. A criminal addict can also be sentenced to undergo deprivation treatment in lieu of a regular statutory penalty for his offense. Furthermore, a suspension for any period up to five years of the right to pursue a certain occupation may be imposed on an addict. Such suspension often is tantamount to an order to change one's occupation, and this provision is one of the most drastic measures in force. Special institutions to which drug addicts may be committed by the courts do not exist.

Among the addicts to whom the mentioned provisions for commitment apply, the small group of physician addicts deserves special attention. A doctor is held to have violated the antinarcotic law if, among other things, he prescribes narcotics for himself "under medically unjustifiable" circumstances, e. g. in order to satisfy an abnormal craving. If the addicted doctor shows no disposition to undergo treatment or to curtail his abuse of the power of prescription, the police, in collaboration with the health authorities, go into action. Within the last four years sixty physicians have been detained in institutions by the courts for considerable periods on account of drug addiction. That this rigorous procedure is effective is attested by the fact that of the doctors released only a few have thus far recidivated although many have been at liberty for years.

If medicolegal opinion decides for the commitment to an institution of a law-breaking addict, the court can order the

prisoner committed on the same day to the hospital section of the examining prison or to any suitable institution. Deprivation therapy is immediately initiated, unmitigated by the use of any palliatives. "The addict is granted no respite from the sufferings incident to deprivation, consequently, the frightful recollection of the cure will remain with him and act as a deterrent." For some months after the first stage of deprivation the patient's habits are slowly changed, and this period is succeeded by an equally long stage of reeducation. The courts are also empowered to commit for treatment the addict whose mental condition on repeated examination so warrants, even if he is not considered a criminal. Such commitments may be either immediate or delayed.

#### RELEASE ON PROBATION

The 'release on probation' of a committed addict is usually considered only after six months has passed since commitment. Experience has shown that deprivation treatment of shorter duration virtually never leads to permanent cure. The patient undergoes an extremely careful examination before a court hearing on the question of release takes place. If expert opinion is favorable the court may grant a release on probation subject to certain 'obligations.' This means that the person released must report regularly for follow-up examination for eighteen months. He reports every fortnight or so at first and then at gradually greater intervals. The police take part in the supervision of erstwhile addicts. Should suspicion of recidivation arise, an intensive investigation is made, inquiry is made at pharmacies and among the person's acquaintances. Should the person actually backslide, a simple court order suffices to cancel his release on probation and to commit him to an institution.

The national center possesses a card index record of commitments and surveillance covering the entire reich. From 1934 to 1937, 289 persons were committed to institutions by court order on account of addiction to narcotics. Of this number 128 were released on probation, ninety-one had to serve out longer sentences and ten died. The number of persons finally released from supervision namely those considered cured, could not be determined, since data concerning them are incomplete. Thomas stated that among the 289 addicts only twenty-seven were known to have recidivated. A difficult problem is presented by those addicts who are not punishable under criminal law but who refuse to submit voluntarily to deprivation therapy. Attempts at supervision by relatives are seldom successful.

#### German Clinics at Prague University

There are two universities at Prague, the German University, one of the oldest in Europe, and the Charles University which is Czech. The years since the establishment of the Czechoslovak state have been marked by numerous disagreements between the two institutions. The German clinics and institutes in particular have complained of their lack of funds and especially of the inadequacy of the aids and subsidies received from the government. During the recent period of political change in Czechoslovakia the German newspapers and medical journals reported the closing of eight of the German university clinics, together with the arrest of certain members of the medical and nursing staffs. It was also stated that care of the patients in these clinics had been assumed by the Czech clinics.

Lately, more precise information has appeared in the German medical press with regard to these occurrences. September 26 the surgical, the first and second medical, the psychiatric neurologic, the otorhinologic and the dermatologic clinics of the German university were discontinued and taken over by the Czechs. October 25 the Czech ministry of education and public health decreed the restoration to their post of the ousted members of the clinical staffs. All these had meanwhile left Prague.

## ITALY

(From Our Regular Correspondent)

Nov 30, 1938

## Congress of Neurosurgeons

The third National Congress of the Società radio-neurochirurgica italiana recently met at Pisa. Professor Ayala, president of the executive committee, in his inaugural speech reviewed the progress of neurosurgery. Modern interpretations of the symptoms of nervous diseases enable neurologists in the majority of cases to make a diagnosis which is verified and sometimes modified by roentgenologists. At the same time refinements in surgical techniques enable surgeons to perform delicate and successful operations on the nervous system which could not have been done a few years ago. Francesco Durante, an Italian surgeon, reported in 1884 a successful operation for removal of a tumor from the frontal lobe. The patient survived the operation for twenty years. The modern operations for diseases of the central nervous system are entirely different from those performed in Durante's time. The so called operative surgery of the nervous system after Chipaut and surgery after prescriptions, according to Cushing's phrase, are no longer in use. Modern operations on the nervous system are mainly to obtain functional restoration of the neuropsychic faculties of the patients. They progress with the greater appreciation of the differences between the nervous system of men and that of experimental animals. The problem of the cerebral localizations in man can be interpreted through the knowledge offered by surgery of the nervous system.

The official topic of the congress was "Diagnostic and Therapeutic Criteria in Cases of Acute Craniocerebral Trauma." Professors Mario Lapidari, Virginio Porta, Mucchi and Carnevali Ricci were the speakers. Trauma from bullets and foreign bodies of violent properties was excluded.

## SURGICAL ASPECTS OF CRANIOCEREBRAL LESIONS

Professor Lapidari said that the seriousness of craniocerebral lesions is not necessarily proportional to that of the lesions of the extracranial soft parts. A diagnosis of the intensity of craniocerebral lesions cannot be made from the external lesion. The treatment of the wound is of surgical importance. The speaker advised immediate treatment, which consists in complete cleaning of the wound, removal of bruised edges, coagulated blood, mortified tissues and foreign bodies, and partial or complete suturing of the wound. Partial suture, occasionally with application of drainage, is indicated in the case of contaminated wounds which are cared for in the first few hours after trauma. The speaker believes that the pathogenic mechanism of fractures of the cranium is different in man and in experimental animals. Therefore the schematic theories on the subject which are based on experimental trauma are far from being exact. Cranial lesions result from different violent actions which take place in succession in the course of trauma. They act on the cranium in different ways. Making a diagnosis of cranial fracture from the clinical symptoms alone is difficult. Still more difficult is the diagnostic interpretation of pain, tumefaction and other local phenomena in the case of exposed cranial fractures with small wounds. The discharge of cerebrospinal fluid through the nose, mouth or ear and the late appearance of ecchymosis on the inclined points of the base are signs of confirmatory diagnostic value with fractures of the base. A certain and grave sign of fracture is collections of air under the skin or under the periosteum of bones which are covering pneumatic cavities, such as the frontal sinuses and the mastoid. Hemorrhages through the nose and mouth have no diagnostic significance. Hemorrhages through the ear are a decisive symptom when they are associated with immediate deafness, facial paralysis and elimination of cerebrospinal fluid through the ear. Fractures of the base do not demand special surgical treatment unless there are complications. The most serious complication is the development of purulent meningitis secondary to fracture of bones over

the natural cavities of the base or secondary to exposed fracture of the vault. The best treatment in such cases is Zeller's, which consists in daily withdrawal of the purulent cerebrospinal fluid and substitution of air (artificial pneumo encephalon) in association with the administration of hypotonic solutions by phlebotomy. Surgical intervention is contraindicated in the presence of cerebral lesions which cause symptoms of diffuse intracranial pressure. Operative trauma aggravates the conditions caused by craniocerebral trauma, and there are doubts as to whether or not the operation will give satisfactory results. It is advisable to administer treatment aimed to diminish hypertension of the cerebrospinal fluid, such as intravenous injections of hypertonic solutions, intestinal derivation and lumbar puncture. The last is effective when the cerebrospinal fluid is replaced by air, the substitution being controlled by a manometer.

## ROENTGENOLOGIC ASPECT OF CRANIOCEREBRAL TRAUMA

Professor Mucchi said that in making the x-ray study of the brain and the cranium in cases of craniocerebral trauma, encephalograms, cerebral arteriograms and iodoventriculograms are necessary. Encephalograms are contraindicated only in rare cases. Cerebral arteriograms are indicated when hemorrhage is suspected. In making a diagnosis of cranial fracture the two lateral and two sagittal projections, the two projections of Schuller and the demaxial, frontonuchal and axial projections are necessary. The fractures which most frequently show in roentgenograms of the cranium are those of the temporal and parietal bones, those of the frontal and occipital bones show less frequently. Fractures of the petrous bone are frequent. Fractures of the anterior cranial fossa and isolated fractures of the base are rare. Encephalographic examination requires the use of at least 100 cc of air. Cerebral edema prevents the passage of air to the subarachnoid spaces which correspond to the involved part of the brain. Internal hydrocephalus can be shown within four or five days after trauma. Cerebral ischemia is shown during encephalographic examination by the passage of air to the subdural spaces because of the presence of a laceration of the arachnoid or some other cause.

## LESIONS OF THE INTERNAL EAR

Prof. Carnevali Ricci discussed the diagnostic and therapeutic criteria of lesions of the internal ear from closed cranial trauma. The most frequent observation is laceration of the tympanic membrane which follows fracture of the temporal bone. A characteristic aspect, aside from the presence of perforation, is the presence of hyperemic zones at the membrane. Otorrhagia is a frequent symptom of fracture of the petrous bone. Elimination of cerebrospinal fluid through the ear takes place in about 4 per cent of the cases. Functional alterations of the labyrinth take place in some cases and are evidenced by dizziness, nystagmus and, occasionally, changes in hearing. The problem of the treatment of fracture of the petrous bone is unsolved. As a rule operation is contraindicated when suppurative otitis media existed before or developed after the fracture.

## Deaths

**Floyd Elwood Keene** ☉ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1904, William Goodell professor of gynecology at his alma mater and professor of gynecology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, member and past president of the American Gynecological Society, past president of the Philadelphia Obstetrical Society, fellow of the American College of Surgeons, served during the World War, gynecologist to the Hospital of the University of Pennsylvania, Bryn Mawr (Pa.) Hospital, Abington (Pa.) Memorial Hospital and the Chestnut Hill Hospital, aged 57, died, Nov. 15, 1938, at his home in Wynnewood, Pa.

**Joseph Millen King** ☉ Los Angeles, University of Southern California College of Medicine, Los Angeles, 1895, clinical professor of medicine at his alma mater, fellow of the American College of Physicians, past president and secretary of the Los Angeles County Medical Society and the Southern California Medical Association, past president of the Los Angeles Clinical and Pathological Society and the California Medical Association at various times on the staffs of the Hollywood Hospital, California Lutheran Hospital and St. Vincent's Hospital, aged 66, died, Oct. 7, 1938.

**Philip Samuel Stout** ☉ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1904, associate professor of otology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otological Society, fellow of the American College of Surgeons, served during the World War, on the staff of the Jefferson Hospital and the Graduate Hospital, aged 61, died Nov. 3, 1938, in St. Luke's and Children's Hospital, of heart disease.

**George Franklyn Inch** ☉ Ypsilanti, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895, member of the American Psychiatric Association, at one time assistant medical superintendent of the Kalamazoo (Mich.) State Hospital, consulting neuropsychiatrist to the U. S. Veterans Bureau, 1920-1926, formerly superintendent of the Traverse City (Mich.) State Hospital, consulting psychiatrist to the Butterworth Hospital, Grand Rapids, since 1931 medical superintendent of the Ypsilanti State Hospital, aged 65, died, Nov. 29, 1938, of heart disease.

**Joseph Coolidge Palmer**, Syracuse, N. Y., Syracuse University College of Medicine, 1903, member of the Medical Society of the State of New York, professor emeritus of hygiene, sanitation and clinical pediatrics at his alma mater, member of the American Academy of Pediatrics, director of health of the city public and parochial schools, served during the World War, on the staff of the Syracuse Memorial Hospital, aged 63, died, Oct. 27, 1938, in the Hospital of the Good Shepherd, Syracuse University, of hypertrophy of the prostate and heart disease.

**William Moore Guilford**, Lebanon, Pa., University of Pennsylvania Department of Medicine and Surgery, Ann Arbor, 1852, member of the Medical Society of the State of Pennsylvania, oldest alumnus of the University of Pennsylvania, past president of the Lebanon County Medical Society, Civil War veteran, for many years member of the city board of health for many years on the staff of the Good Samaritan Hospital, aged 106, died, Dec. 10, 1938, of pneumonia.

**John Henry Neff** ☉ Charlottesville, Va., University of Virginia Department of Medicine, Charlottesville, 1910, professor of urology at his alma mater, member of the Southern Surgical Association, American Association of Genito-Urinary Surgeons, American Urological Association and the Clinical Society of Genito-Urinary Surgeons, past president of the Virginia Urologic Society, on the staff of the University of Virginia Hospital, aged 51, was found dead, Nov. 9, 1938, in a pond.

**Ulysses J. Grim**, Waukegan, Ill., Rush Medical College, Chicago, 1891, professor emeritus of otorhinolaryngology, Loyola University School of Medicine, Chicago, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, on the staffs of the Illinois Eye and Ear Infirmary and the Mercy Hospital, Chicago, aged 72, died, Oct. 8, 1938, in St. Therese's Hospital, of heart disease.

**Benton Elkins Longwell** ☉ Johnstown, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1899, past president and secretary of the Cambria County Medical Society, fellow of the American College of Surgeons, on the

staff of the Conemaugh Valley Memorial Hospital, at one time member of the board of health and school board of West Mount, aged 64, died, Oct. 11, 1938, of acute pyelonephritis.

**George C. Webster Jr.**, Chester, Pa., Jefferson Medical College of Philadelphia, 1913, member of the Medical Society of the State of Pennsylvania, served during the World War, on the staff of the J. Lewis Crozer Home for Incurables and Homoeopathic Hospital, aged 50, died, Oct. 23, 1938, of cardiovascular sclerosis, multiple cerebral hemorrhage and chronic nephritis.

**William Ide Tomlinson**, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1903, associate professor of obstetrics at his alma mater, fellow of the American College of Surgeons, on the staffs of the Hahnemann Hospital and the Broad Street Hospital, aged 57, died, Oct. 14, 1938, of coronary thrombosis, pulmonary embolism and lobar pneumonia.

**Walter Kempster Gray** ☉ Milwaukee, University of Arkansas School of Medicine, Little Rock, 1918, member of the American Urological Association, served during the World War on the staffs of the Mount Sinai Hospital and the Columbia Hospital, aged 58, died, Oct. 20, 1938, of an injury to the right leg.

**John Wesley Ellis**, Lampasas, Texas, St. Louis University School of Medicine, 1905, member of the State Medical Association of Texas, served during the World War, aged 61, died Oct. 26, 1938, in the Veterans Administration Facility, Legion of arteriosclerosis.

**Charles Ransom Draper**, Medford, Mass., University of Vermont College of Medicine, 1888, member of the Massachusetts Medical Society for many years on the staff of the Lawrence Memorial Hospital, aged 75, died Oct. 25, 1938, of hypertensive heart disease.

**Harris M. Branham**, Brunswick, Ga., College of Physicians and Surgeons, Baltimore, 1888, member of the Medical Association of Georgia for many years chairman of the county board of health, aged 76, died, Oct. 28, 1938, of cerebral hemorrhage and chronic myocarditis.

**Charles Monroe Kennedy** ☉ Camden, Ind., Medical College of Indiana, Indianapolis, 1905, bank president, at one time county coroner, aged 63, died, Oct. 28, 1938, in the Cass County Hospital, Logansport, of coronary occlusion and pulmonary embolism.

**William Moore**, New Albany, Ind., University of Louisville (Ky.) Medical Department, 1884, member of the Indiana State Medical Association, on the staff of St. Edwards Hospital, aged 86, died, Oct. 8, 1938, of cerebral hemorrhage and acute bronchitis.

**Ignatius L. Goodfried** ☉ New York, Baltimore University School of Medicine, 1898, formerly on the staff of the Mount Sinai Hospital, aged 61, died Oct. 24, 1938, in the Beth David Hospital, of myocarditis, chronic bronchiectasis and carcinoma of the liver.

**Otto Carl Ahlers** ☉ Sherman, Texas, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897, chairman of the board of trustees of the Wilson N. Jones Hospital, aged 66, died, Oct. 30, 1938, of cerebral hemorrhage.

**Frank Eliot Stetson**, South Dartmouth, Mass., Harvard University Medical School, Boston, 1897, formerly member of the board of health of New Bedford, served during the World War, aged 69, died, Oct. 20, 1938, of coronary sclerosis.

**Frank Blaney Eaton**, Portland, Ore., Cooper Medical College, San Francisco, 1875, aged 86, died, Oct. 10, 1938, in a hospital at Glendale, Calif., of cerebral hemorrhage.

**Charles Ellsworth Hewitt**, Mystic, Conn., Hahnemann Medical College and Hospital of Philadelphia, 1893, aged 83, died, Oct. 1, 1938, of pulmonary hemorrhage.

**Franklin Arthur Heckler**, Columbus, Ohio, Ohio Medical University, Columbus, 1895, aged 71, died, Oct. 17, 1938, in the Grant Hospital, of cerebral hemorrhage.

**John Thomas Stanford**, Philadelphia, Howard University College of Medicine, Washington D. C., 1895, aged 78, died, Oct. 30, 1938, of cerebral hemorrhage.

**John M. Johnson**, Frankfort, Ind., Curtis Physio Medical Institute, Marion, 1894, aged 80, died, Oct. 21, 1938, of carcinoma of the stomach.

**Humie Zebie Lee Horton**, Apex, N. C., Medical College of Virginia, Richmond, 1923, aged 41, died, Oct. 27, 1938, of acute myocarditis.

**Isaac N. Rogers**, Rogersville, Mo., St. Louis Medical College, 1872, aged 88, died, Oct. 12, 1938, of bronchopneumonia.

## Bureau of Investigation

### AN OBESITY CURE FRAUD

Nancy Hatch and Youthful Face and Figure, Inc.,  
Barred from the Mails

The "obesity cure" racket is not what it used to be. A few years ago there was a veritable flood of fakes—most of them merely worthless but some of them viciously dangerous—sold to the overweight by those who were literally living on the fat of the land.

Among the more conspicuous humbugs in the fat-cure field were certain pastes and soaps that were sold under the claim that, by rubbing them on the body surface, adipose tissue could be effaced. While the preposterousness of such claims was obvious to physicians, the "stylish stout" with a strongly developed "will-to-believe" fell hard for them. It was useless to tell such people that there was no paste or soap that, rubbed on the body, would remove fat. The advertisements in certain magazines and newspapers said that they would—and that was that.

Among some of the paste or soap types of obesity cures that were investigated by the Bureau of Investigation of the American Medical Association and the results published either in this department of THE JOURNAL or in *Hygienics* were the following:

**Absorbit**—A paste consisting of lard oil beeswax and a small amount of ox bile.

**Lutol**—A paste containing 10 per cent soap and 90 per cent water.

**Folt's Reducing Soap**—An artificially colored soap containing a minute amount of iodine.

**LaMar Reducing Soap**—A soap to which small amounts of saffron and potassium iodide had been added.

**Morlene**—A gelatinized mixture of alcohol soap sodium iodide and sugar.

**Nature's Way Reducing Cream**—Petrolatum mineral oil beeswax, epsom salt baking soda and alum.

**Stendiform**—An emulsion of casein oil of turpentine and white vinegar.

It is doubtful whether any of the fakes just listed are still advertised, although some of them may still gather dust on the druggists' shelves. But that external obesity "cures" are not yet entirely extinct is evident from the facts given not many weeks ago in a memorandum to the Postmaster General from the office of the Solicitor to the Post Office Department, recommending the issuance of a fraud-order against a concern doing business under the trade names "Nancy Hatch" and "Youthful Face and Figure, Inc."

The information that follows is from the memorandum just referred to or from material in the files of the Bureau of Investigation of the American Medical Association. The fraud in question was conducted by Mrs. Nancy Hatch Herbert and her son John L. Hatch. The business was started about 1930 and was incorporated in 1937 and capitalized at \$10,000. Stock to the amount of \$7,500 was issued and was held by the Herbert woman and her son John L. Hatch. Victims were obtained in the orthodox way—by advertising in those magazines and newspapers that obviously do not have the welfare of their readers at heart. A typical advertisement is reproduced herewith.

Some of the earlier advertisements were even more blatant. One stated that Dr. Hatch's Reducing Cream—later called Dr. Hatch's Formula Massage Cream—would cause the overweight to reduce even though you "Eat what you like, take no exercise or drugs." Still another advertisement, instead of giving the name of the product and the address at which it could be obtained, was run in editorial style and was ballyhooed by the "Beauty Department" of *Mother's Home Life*, Winona, Minn. Those who wrote to the "Beauty Department" were sent the Hatch advertising circulars.

Purchasers of the Hatch nostrum (\$1 for a half-pound package) received a jar of pinkish paste and some dietary instructions. This in spite of the fact that the obese public was led to believe from the Hatch advertising that dieting and exercise were unnecessary when Dr. Hatch's Formula Massage Cream was used. Government chemists analyzed the "cream" and reported that it was more than 99 per cent soap and water with a dash of epsom salt and a trace of iodine. There should have been money in the sale of soap at \$2 a pound!

The quacks who put out this fraud had a physician appear as a witness for them at the government hearing. One K. Arvid Enlind, M.D. According to the records Dr. Enlind was born in 1873 and holds a diploma from the College of Physicians and Surgeons of Baltimore, 1893, he was licensed in Connecticut in the same year, in New York in 1907 and in the District of Columbia in 1931. He is not a member of the American Medical Association. The files of the Bureau of Investigation of the American Medical Association show that in 1912 Dr. K. Arvid Enlind was endorsing "Vegatal Crackers" for "autointoxication and constipation."

In 1936 the National Better Business Bureau, a militant crusader against fraudulent advertising, wrote to the Bureau of Investigation of the American Medical Association and asked for information regarding "Youthful Face and Figure Institute," as the concern was then known. The Better Business Bureau stated that the "Institute" had sent it a statement signed K. Arvid Enlind, M.D., reading as follows:

"It is my opinion that Dr. Hatch's Formula Massage Cream contains elements which have definite reducing properties when applied to the surface of the body. These elements are Iodine and Epsom Salt, and have an oxidizing effect on the superficial fat. This cream is absolutely harmless to anyone regardless of their physical condition."

At the Post Office hearing Dr. Enlind testified that he did not know the percentage of the various ingredients used in the Dr. Hatch's Formula Massage Cream but that he was sure that this soap-and-water paste would cause a reduction in weight if rubbed on the body. In fact, on cross examination he testified

ADVERTISEMENTS PLEASE MENTION JULY MOTION PICTURE 75

that the only effective ingredients in the paste were the soap and water! As a matter of social hygiene it may be admitted that any one who needs to reduce weight by using soap and water should not be deterred. But the result can be accomplished much more cheaply and efficiently by taking a bath.

In order, presumably, to catch the gullible both coming and going, the Hatch quackery also included a preparation to be taken internally called "Slimmets." The Hatch concern was reported in 1937 by the Federal Trade Commission to have stipulated that it would discontinue advertising that either the "Cream" or "Slimmets" would remove adipose tissue without the need of dieting. But apparently the Federal Trade Commission was not taken very seriously, as the company was still making such representations as late as March 1938 when cited by the Post Office Department.

Not long ago that department debarred from the mails a fraud that was supposed to cure errors of refraction and make the use of glasses unnecessary. It was brought out at the hearing that the exploiter of the fraud wore glasses! In the same spirit of *tu quoque*, the memorandum of Acting Solicitor Calvin W. Hassell to the Postmaster General in the Hatch case brings out the fact that although Mrs. Nancy Hatch Herbert and her medical witness, Dr. Enlind, both testified that they used the "cream" yet "Despite this fact, when they took the witness stand, it was evident they were both considerably overweight."

On the recommendation of the Acting Solicitor who had studied the evidence and was convinced of the fraudulence of the scheme the Postmaster General on July 11, 1938, issued a fraud-order debarring from the mails "Youthful Face and Figure, Inc.," and "Nancy Hatch" and their officers and agents as such.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### HEADACHE AFTER SPINAL ANESTHESIA

To the Editor—Headache is a not infrequent complication following spinal anesthesia. Can you enlighten me as to the present consensus concerning the etiology and treatment of this condition?

M. D. Pennsylvania

ANSWER—According to Pelouse (Postspinal Anesthetic Headache, *Illinois M J* 67 372 [April] 1935) headache may be expected in from 15 to 25 per cent of cases after diagnostic spinal punctures and in only about 3 per cent after spinal anesthesia, if the careful present day technique is used. The headache seems to be the result of prolonged seepage of spinal fluid from the puncture wound in the dura and arachnoid. Other factors, such as sex, weight, temperament, amount of fluid withdrawn, difficulty of inserting the needle, the presence or absence of fresh blood in the fluid withdrawn, the position of the patient during puncture, the pressure of fluid and the drug used are not the causes of headache. Two types of headache are cited: type A, that caused by decrease of cerebrospinal fluid and type B, that caused by increase of fluid. With loss of fluid the brain rests uncushioned on the venous plexus at the base of the skull, causing venous congestion and a resulting headache. One author suggested that the formation of fluid is speeded up during seepage and when the hole finally closes excess secretion continues for a time, causing increased cerebrospinal pressure and headache. Headache of type B caused by increased fluid is usually ascribed to a mild meningitis. In cases of headache of type A, lumbar puncture shows decreased fluid pressure and a decreased value for globulin and decreased cell count. In cases of headache of type B, a puncture will show increased fluid pressure with an increased amount of globulin and an increased cell count. Type A headaches are relieved by lowering the head, and usually no sedative will relieve them sufficiently for the patient to be erect and work. Type B headaches are not relieved by lowering the head but are relieved by drugs. Besides position, headaches of type A are best treated by quiet, sedatives, forcing of fluids by mouth, intravenous administration of hypotonic saline solution, ephedrine and solution of posterior pituitary. Some investigators advocate intraspinal administration of physiologic solution of sodium chloride or 1 per cent dextrose solution, the latter giving more lasting benefit. Treatment of headaches of type B demands sedatives, recumbency, limited amounts of fluids, diuretics, cathartics and repeated lumbar punctures.

One of the kindest things one can do for a patient who has headache after lumbar puncture is to assure him that the headache will not be permanent. The patient often becomes so alarmed that the headache is aggravated by his worry. It is probable that headache would occur after lumbar puncture in many cases were it not for the fact that the patient's head is not raised until two or three weeks after the operation. In general the incidence of headache of this type probably is not less than 5 per cent. Headache after lumbar puncture usually may be considered a contraindication to the subsequent use of spinal anesthesia.

### PSORIASIS AND ALLERGY

To the Editor—A married woman aged 37 has had psoriasis badly for at least twenty years. The lesions were especially severe under the breasts causing her a great deal of discomfort. She had treatments including x-rays by a competent dermatologist which eased the condition slightly but not much. She also has had hay fever due to ragweed sensitivity. This past season I induced her to try some ragweed pollen desensitization treatment. I followed the usual course of immunization using Squibb's pollen extract and after about the fifth injection she noticed that her psoriasis was improved and after the tenth injection it has entirely disappeared and has not recurred as yet. As a rule the lesions would be much worse at this time of year when her hay fever was worse although she has the psoriasis all the year round. Could there be any connection between the psoriasis and the ragweed sensitivity? I would appreciate any information as to the possible mechanism of the effect of the ragweed pollen extract on the psoriasis.

ERNEST P. SMITH, M.D., Cohocton, N. Y.

ANSWER—The relationship between psoriasis and such allergic conditions as hay fever has been considered by many workers. The fact that this patient's psoriasis cleared up during a course of injections of pollen extract does not, of course, prove that psoriasis is an allergic condition. Several possibilities exist.

First, spontaneous remission may have occurred. Second, pollen extracts, which contain protein, may have acted nonspecifically. Many cases of psoriasis have been temporarily relieved by such nonspecific protein therapy as injections of boiled milk. The third possibility is that psoriasis may actually be an allergic disease. The fact that most patients with psoriasis improve in the summer, especially after exposure to sunlight, speaks against any relationship to pollen, which, of course, is prevalent only in warm weather. This does not prove that psoriasis may not be related to some nonpollen form of allergy.

Zeidler (*Wien med Wchnschr* 81 877 [June 27] 1931) found that some patients with psoriasis and hay fever had relief from their cutaneous condition by injections of pollen extract. He showed that normal persons give uniformly negative reactions to pollen extracts, patients with psoriasis frequently give positive tests for pollens, clinically 22 per cent of his psoriatic patients had nasal symptoms typical of hay fever or rhinitis.

Brock (*Munchen med Wchnschr* 77 2225 [Dec 26] 1930) believes that asthma, gout and psoriasis are often associated and calls the triad 'visceral gout'. He found that treatment for gout brought on improvement in the asthma and psoriasis.

Mienicki and Ryll-Nardzewski (*Dermat Wchnschr* 97 1688 [Dec 2] 1933) believe that psoriasis is allergic and report that patients with psoriasis react with anaphylactoid shock to intracutaneous injections of an antigen. They used emulsion vaccine and cultures of *Staphylococcus aureus* and had positive reactions in one third of the cases.

From a study of the literature no definite conclusions can be made at the present time, it would seem that the burden of proof rests on those who are attempting to put psoriasis in the group of allergic conditions.

### PNEUMOCOCCUS ANTIGEN IN CCC CAMPS—SULFAPYRIDINE IN PNEUMONIA

To the Editor—1. Will you please tell me what the results of army antipneumococcus vaccine are which I understand has been used in the CCC camps for some time? 2. Also have you any reports on the use of a sulfanilamide derivative in the treatment of pneumonia?

THOMAS J. WEST, M.D., Pasadena, Calif.

ANSWER—1. The results of experiments using a pneumococcus antigen in CCC camps during the winter of 1936-1937 have recently been published (Ekwurzel, G. M., Simmons, J. S., Dublin, L. I. and Felton, L. D. VIII Report on Field Tests to Determine the Prophylactic Value of a Pneumococcus Vaccine, *Pub Health Rep* 53 1877, 1891 and 1892 [Oct 21] 1938). The report concludes:

(a) Thus the findings of the 1936-37 experiments are consistent with the impressions gained from the other preliminary experiments. Taking all the experiments together, it appears that this or a similar antigen may prove to be a useful tool for the control of pneumonia incidence. However, this statement must be qualified by the two considerations set forth under b and c below. It should be mentioned incidentally, that there were too few deaths upon which to base any conclusions regarding the effect of the antigen on the case fatality from pneumonia.

(b) The present experiments provide no indication as to the length of time for which the inoculations of antigen may influence the pneumonia morbidity rates.

(c) There is some indication that the antigen may be most effective for adolescents and that it loses its effectiveness with advancing age. It was found in the New England camps that at ages under 20, the pneumonia incidence rate in the control group was 27 times that in the inoculated group, at ages 20 to 24, the ratio was 14, and at ages 25 to 49, the inoculated enrollees actually experienced a higher rate than the control group.

It is safe to accept the conclusion that "the results of the present surveys indicate the need for additional investigations."

2. The sulfanilamide derivative referred to is probably 2-(p-aminobenzenesulfonamido) pyridine, for which the Council on Pharmacy and Chemistry has coined the name sulfapyridine (see page 49, this issue). The product was introduced also under the unfortunate names Dagenan and M & B 693. Whitby (Chemotherapy of Pneumococcal and Other Infections, *Lancet* 1 1210, 1212 [May 28] 1938) reported on experiments in mice. If one were to apply strictly the mouse experiments of Whitby a man of average weight would have to be given 90 Gm of sulfapyridine a day for six days. However, by giving from 1 to 15 Gm of sulfapyridine six times a day by mouth, concentrations as high as 6 or 8 mg per hundred cubic centimeters have been obtained in the blood. The report of Evans and Gaisford (Treatment of Pneumonia with 2-(p-Aminobenzenesulfonamido) Pyridine, *Lancet* 2 14 [July 2] 1938) is unconvincing because their cases were not typed nor otherwise adequately classified.

The apparently favorable effect may have been due to chance in sampling, and one group may have contained many more older patients and the other more patients with less virulent types. In "Pneumococcal Septicemia" by Dyke (*Lancet* 2 621 [Sept 10] 1938) the type was undetermined, it was not pneumococcus I, II, III or VII. Dyke and Reid (Treatment of Lobar Pneumonia with M & B 693, *Lancet* 2 1157 [Nov 19] 1938) reported eight cases of patients of various ages and with various types of the disease, in some the type was not determined. Flippin and Pepper reported two cases in young men with pneumococcus type I and pneumococcus type VIII (The Use of 2-[*p*-Amino-benzene-sulfonamido] Pyridine in the Treatment of Pneumonia, *Am J M Sc* 196 509 [Oct] 1938).

Since its introduction, too short a time has elapsed for adequate study, and at the present time there is no conclusive evidence that sulpyridine is of value in the treatment of the pneumonias in man, though informal reports made so far indicate encouraging results.

Every one agrees that different pneumococci produce pneumonias with characteristic mortality rates. It is poor medicine to compare two groups of 100 cases of acute pulmonary inflammation or pneumonia without reference to the type of pneumococcus, if it is the cause, or the other factors which determine the fatality rate.

To reach a conclusion concerning the value of this or other therapy for pneumonia, one must learn whether among the patients who receive the treatment more lives are saved and whether there is less bacteremia and fewer complications than among those from whom it is withheld. So far the product has not been licensed by the Federal Food and Drug Administration for sale in interstate commerce.

The advisory committee on pneumonia control of the New York State Department of Health believes that the evidence of the safety and therapeutic value of sulpyridine in the treatment of any of the various types of pneumococcal pneumonia is at the present time inconclusive. According to a resolution adopted by the committee at a meeting December 16, the committee further believes that the distribution of this drug should be restricted to experimental centers having facilities for careful study of toxicity and therapeutic efficiency until adequate evidence of the safety of the use of the drug and its therapeutic efficiency has been obtained. Members of the advisory committee are Drs. Russell L. Cecil, New York, chairman, Donald B. Armstrong, Peter Irving and Ralph S. Muckenfuss, New York, Rufus I. Cole, Mount Kisco, Thomas P. Farmer, Oliver W. H. Mitchell, Syracuse, Clayton W. Greene, Buffalo, George M. Mackenzie, Cooperstown, William S. McCann, Rochester, George H. Ramsey, White Plains, and Augustus B. Wadsworth and Arthur W. Wright, Albany.

#### DRIED PITUITARY SNUFF FOR PEPTIC ULCER

*To the Editor*—A large number of people in this locality have read the press reports from the doctors of the University of Texas in the treatment of peptic ulcers with the snuff cure (pituitary glands). It appears from the press report that about 90 per cent of the patients or in other words of the sixty patients who have used the snuff fifty four have been relieved and the x-ray examinations showed no evidence of a peptic ulcer. Is this publicity authentic?

J. S. COLLINS M.D. Wabasha Minn.

*To the Editor*—Have you any information about the use of posterior pituitary substance in powder form intranasally in the treatment of peptic ulcer? Where can it be obtained?

JANE LOCKWOOD, M.D. Greenwich Conn.

*To the Editor*—Will you please send me some information about an article appearing in *Time* by M. Hill Metz, M.D. and Robert W. Lackey, Ph.D. from Baylor University on the use of ground dried pituitary to snuff in treatment of ulcer? All the ulcer patients in town must have read it. Is its value proved?

JOHN L. SULLIVAN M.D. Elyria Ohio

**ANSWER**—Drs. Metz and Lackey of Baylor University reported a method of treatment of peptic ulcer by inhalation of the dried powder of posterior pituitary extract. This powder was sprayed on the nasal mucous membranes of patients definitely diagnosed with ulcer and they noted improvement in a certain number of cases. They also gave subcutaneous injection of the extract. Posterior pituitary extract is of known value in diabetes insipidus. They noted that a number of their ulcer-bearing patients have an increased urinary output with an increased night volume of low specific gravity, however, to a lesser extent than in diabetes insipidus. These urinary symptoms disappeared when treatment with posterior pituitary extract as outlined was given, and in addition there was relief from the ulcer symptoms. In a group of forty-two patients marked relief was noted in from one to eight days. Seven patients with chronic lesions continued to have slight symptoms after one month. The mode of action is not known. Fluoroscopic exami-

nation revealed a decrease in tone in the entire viscus and a reduction in spasm and motility. Therefore the stomach empties more slowly. This work is still on an experimental basis and cannot be suggested as an approved method of therapy today. The articles by Metz and Lackey appeared in the *Dallas Medical Journal* 24 46 (April) 1938 and the *Texas State Medical Journal* 34 214 (July), 295 (Aug) 1938.

#### TREATMENT OF SONNE DYSENTERY

*To the Editor*—A white man aged 27 gives a four months history of recurrent fever, general aching, cramps of the bowel and frequent loose slightly blood tinged stools. He has worked except for short periods of illness but has not felt well any of the time. The laboratory reported isolation of *B. dysenteriae* Sonne. Other routine and special tests were negative. I am unable to locate specific serum. Facilities make autogenous serum practically impossible. Can I obtain the specific serum anywhere? Will an autogenous vaccine effect a cure when used in conjunction with local therapy? Is there any report of the use of sulfanilamide in the treatment of the dysenteric group? M.D. New York.

**ANSWER**—There is no Sonne specific antidysenteric serum manufactured. A polyvalent serum that contains Sonne strain antibodies is obtainable from Sharp and Dohme in 20 and 50 cc ampules and is for intravenous use. Sensitivity to horse serum should be ruled out before the treatment is undertaken and, if it is required, desensitization should be performed. The serum should be given daily intravenously the dosage being increased from 10 to 50 cc daily. Thereafter subcutaneous injection of all autogenous vaccine of 1,000 million organisms per cubic centimeter should be started. The initial dose of 0.05 cc. is increased by that amount three times a week for three weeks. Thereafter biweekly or weekly injections with a maximum dosage of 1 cc. should be given. During the course of the treatment the causative organism may disappear from the stool although some bowel symptoms may persist. The treatment must be followed out until all symptoms have disappeared completely. Favorable case reports in which sulfanilamide has been used have not been found.

#### REFRACTORY GONORRHEAL VAGINITIS IN YOUNG GIRL

*To the Editor*—A girl aged 10 years had gonorrheal vaginitis with a moderate discharge in April 1938. The treatment has been as follows: 1. From April 28 to May 30 ten injections of 2,000 units of theelin. Clinical improvement followed but smears were positive. 2. From May 30 to June 29, 50 grains (3.25 Gm.) of sulfanilamide the first and second days 40 grains (2.6 Gm.) from the third to the seventh day and 30 grains (2 Gm.) from the eighth to the twenty first day. The sulfanilamide had to be discontinued for a few days because of fever. 3. From June 30 to August 20 theelin suppositories 2,000 units (thirty). 4. From August 20 to October 11 2 per cent mild protein silver instilled into the vagina nightly. In spite of this treatment smears continue to show gram negative and a few gram positive diplococci but practically no pus cells. Clinically there is only slight redness. A few years ago a sister, three years older had the disease but smears are continually negative for her. She was treated among other things the parents state with phenylmercuric nitrate. What strength should be used? The source of infection seems to be at school. What is your recommendation for further treatment? Is it apt to be contagious now? M.D., Indiana.

**ANSWER**—It must first be decided whether the present status indicates a persisting gonorrheal infection or whether it is due to chemical irritation from too much treatment. "Gram-negative diplococci" are not necessarily gonococci. The accepted standard for a positive diagnosis is the finding of more than ten typical gram-negative diplococci intracellularly in the same slide, and two or more within the same cell.

If a positive diagnosis has been made by this standard, the treatment at this stage consists in eradicating the focus responsible for the persistence of the infection. To eliminate an exogenous focus the entire family, male and female, must be examined for gonorrhea. Reinfection in the school can be avoided by the use of underclothing or bloomers which protect the vulva adequately, and by avoiding contact of the vulva with toilet seats. Endogenous foci are usually found in the urethra, rectum or cervix by means of local inspection and smears taken from these locations. Gonorrheal proctitis and urethritis usually respond to locally applied protein silver compounds. Examination of the cervix is not difficult through a lighted No. 30 endoscope. Cervical erosions or granulations often indicate active infection and respond to several applications of 5 per cent silver nitrate.

If no foci are found, complete cessation of treatment is indicated because of the probability that the persistence of the infection, either specific or nonspecific, is due to overtreatment. Strenuous activity should be avoided during this rest period. If after six weeks the smears are still positive, the most hopeful treatment is the instillation of protein silver in a water soluble

base, such as tragacanth or gelatin. The technic of this treatment is described by Reichert, Epstein Jung and Colwell in the *American Journal of Diseases of Children* (54:459 [Sept.] 1937). Phenylmercuric nitrate ointment 1:1,500 occasionally gives good results. It produces a local irritation in about 2 per cent of the cases. As long as gonococci are present in the smears, the condition should be considered to be contagious.

It must be remembered that gonorrheal genital infection in girls subsides spontaneously at an early stage of puberty.

### PAROXYSMAL TACHYCARDIA

*To the Editor*—A youth aged 18 had an attack of paroxysmal tachycardia while playing football. He had never had any illness prior to this attack and as far as he knew was in good physical condition. The duration of the attack was 219 hours. Normal rhythm was resumed suddenly. What is the longest record for the duration of an attack of paroxysmal tachycardia? Diagnosis was made by five electrocardiographic tracings. Any information as to the average duration of these attacks will be appreciated for this is the longest one I have any knowledge of. The patient was given about 25 grains (1.6 Gm.) of digitalis the first two days as it was thought to be auricular flutter; then he was given small doses of quinidine by mouth. Six days before normal rhythm was established he was given 40 grains (2.6 Gm.) of quinidine in twenty-four hours and the following day he was given 50 grains (3.25 Gm.) with no effect. Two days following he did not get any quinidine and thirty-six hours before normal rhythm returned he was given 5 grains (0.3 Gm.) of quinidine every hour.

M. D. GEORGI

*ANSWER*—The average duration of attacks of paroxysmal tachycardia would probably be measured in minutes, although it has never been calculated. It is highly probable that many cases of extremely short duration are never seen by physicians and this would of course, materially affect any calculation of the average duration. It is usually expressed as varying from a few seconds to a few hours. Only rarely do attacks last longer than from ten to fourteen days. There are two cases on record which in their later years were electrocardiographically characteristic, which lasted fifteen and forty-three years respectively. The propriety of the word "paroxysmal" was properly questioned by the authors who discussed these cases but in one of them a transient reversion to a normal rhythm occurred after a coronary occlusion. A few attacks with durations measured in months are recorded in the literature.

### CELLULITIS OF FACE

*To the Editor*—I would appreciate information on the use of roentgen therapy in acute cellulitis of the face particularly in the butterfly area. Is this method of treatment desirable in preference to incision and drainage? A recent case in which there was edema of one entire half of the face complicating an initial acute cellulitis has prompted this inquiry.

JOHN M. SMITH, M.D., Port Neches, Texas

*ANSWER*—It is the consensus at present that furuncles and cellulitis of the upper lip, nose and middle portion of the face should be treated conservatively. Ayres published the replies to a questionnaire sent to surgeons and dermatologists. The majority believed that incisions and manipulation were to be discouraged. The use of moderate doses of x-rays in these cases is often distinctly helpful and at times causes a speedy involution of furuncles and carbuncles. For technic and methods see "X-Rays and Radium in Diseases of the Skin" by G. M. MacKee, Philadelphia, Lea & Febiger, 1938. Pertinent material to this discussion is contained in an answer to a previous query (Face Infections and Intracranial Complications, THE JOURNAL, Sept. 24, 1938, p. 1231).

### COLOSTOMY

*To the Editor*—What percentage of colostomies close up and what percentage remain as a fistula?

T. J. H. GORRELL, M.D., Chicago Heights, Ill.

*ANSWER*—A well performed colostomy will remain open until it is closed. The exception would be a cecostomy in which a tube was inserted into the bowel to decompress it in acute obstruction, after removal of the tube such a colostomy will usually close. In the performance of a permanent colostomy the bowel is brought outside the abdomen so that the mesenteric border of the bowel between the afferent and the efferent loop forms a support which diverts the fecal stream outward and prevents it entering the distal loop. This type of colostomy will remain permanently open.

### BITTER SKIN FROM RUBBING ALCOHOL

*To the Editor*—The answer to the question of M. D. Ohio regarding bitter skin from drugs (THE JOURNAL, Oct. 29, 1938, p. 1684) may be found from the use of rubbing alcohol for and following the bath. This preparation leaves a persistent and bitter taste which resists even ordinary soap and water.

JOHN V. BARROW, M.D., Los Angeles

#### NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL December 31, page 2210.

### Georgia October Examination

Mr. R. C. Coleman, joint-secretary, State Examining Boards reports the written examination held by the Georgia State Board of Medical Examiners at Atlanta, Oct. 11-12, 1938. The examination covered ten subjects and included 100 questions. An average of 80 per cent was required to pass. Five candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.
Emory University School of Medicine		(1933-3)
Tulane University of Louisiana School of Medicine		(1938)
Harvard University Medical School		(1936)

**Connecticut Homeopathic Report**

Dr Joseph H Evans, secretary, Connecticut Homeopathic Medical Examining Board, reports the written examination held at Derby, July 12, 1938. The examination covered seven subjects and included seventy questions. An average of 75 per cent was required to pass. One candidate was examined and passed. Two physicians were certified for endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad	Per Cent
New York Medical College and Flower Hospital		(1937)	78.9
School	PASSED	Year Endorsement Grad	of
New York Homeopathic Medical College and Flower Hospital		(1928)	New York
Hahnemann Med College and Hospital of Philadelphia		(1921)*	Delaware

\*License has not been issued

**Connecticut July Examinations**

Dr Thomas P Murdock, secretary, Connecticut Medical Examining Board, reports the written examination held at Hartford, July 12-13, 1938. The examination covered nine subjects and included seventy questions. An average of 75 per cent was required to pass. Forty-two candidates were examined, thirty-one of whom passed and eleven failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine		(1937)	75*
76.4 77.5			
Loyola University School of Medicine		(1937)	76.3
Northwestern University Medical School		(1938)	76.2
Rush Medical College		(1937)	76.3*
University of Maryland School of Medicine and College of Physicians and Surgeons		(1938)	76.4
Harvard University Medical School	(1935) 79.4	(1936)	77.8
Tufts College Medical School	(1937) 79.6 83.6*	(1938)	75 77.3*
Cornell University Medical College		(1938)	79.4
New York University College of Medicine	(1937) 75	(1938)	84.3
Jefferson Medical College of Philadelphia		(1936)	75
(1937) 75 77.6* (1938) 75*			
Temple University School of Medicine		(1937)	79.6
University of Vermont College of Medicine		(1937)	75.8
79.4 (1938) 84.4			
Queen's University Faculty of Medicine		(1937)	75
University of Toronto Faculty of Medicine		(1930)	75.5
Medizinische Fakultät der Universität Wien		(1932)	75
Friedrich Wilhelms Universität Medizinische Fakultät Berlin		(1920)	75.2
Regia Università degli Studi di Roma Facoltà di Medicina e Chirurgia		(1934)	76.3
Regia Università di Napoli Facoltà di Medicina e Chirurgia		(1935)	75

School	FAILED	Year Grad
St. Louis University School of Medicine		(1937)
Creighton University School of Medicine		(1937)
Université de Paris Faculté de Médecine		(1926)
Friedrich Wilhelms Universität Medizinische Fakultät Berlin		(1922)
(1936)		
Ludwig Maximilians Universität Medizinische Fakultät München		(1922)
Universität Rostock Medizinische Fakultät		(1936)
National University of Athens School of Medicine		(1930)
Regia Università degli Studi di Padova Facoltà di Medicina e Chirurgia		(1934)
Regia Università di Napoli Facoltà di Medicina e Chirurgia		(1936)
Osteopathy		

Twenty-eight physicians were successful in the oral examination held for endorsement applicants at Hartford, July 26. The following schools were represented:

School	PASSED	Year Endorsement Grad	of
Stanford University School of Medicine		(1929) N	B M Ex
Yale University School of Med (1934) (1936)	(1936)*	(1937) 2) N	B M Ex

# Book Notices

**The Chemistry of the Amino Acids and Proteins** Edited by Carl L. A. Schmitt M.S. Ph.D. Professor of Biochemistry University of California San Francisco Cloth Price \$7.50 Pp 1031 with 259 illustrations Springfield Illinois & Baltimore Charles C Thomas 1938

It is a surprising fact, considering the important part which proteins play in all types of biologic phenomena, that there are so few books, especially in English, dealing with this important class of substances. One reason for this lack of satisfactory books on the subject is undoubtedly that most of the work on the physicochemical properties of amino acids and proteins, which forms the basis for modern protein chemistry, has been done within the last twenty years. Another reason is that the subject is so vast, and is developing so rapidly, that there are few persons competent to handle it adequately. In this volume the latter difficulty has been surmounted by dividing the work among sixteen contributors whose scientific interests lie in the field of amino acids and proteins. The book contains eighteen chapters, many of which are further subdivided into numerous sections. The broad scope of the work may perhaps be best indicated by listing the chapter headings, as follows: historical, the constitution and synthesis of the amino acids, the isolation of the amino acids from proteins, methods of analysis and reactions of the amino acids and proteins, relation of the amino acids to products of biochemical importance, peptides, peptidases and diketopiperazines, the chemical constitution of the proteins, molecular weights of the proteins, certain chemical and physical characteristics of the proteins, optical properties of amino acids and proteins, amphoteric properties of amino acids and proteins, electrochemistry of amino acids and proteins, combination of amino acids and proteins with acids, bases, heavy metals and other compounds, membrane equilibria, some thermodynamical considerations of amino acids, peptides and related substances, dipolar ionic structure and solubility of amino acids, peptides and proteins, relation of proteins to immunity, the role of proteins in nutrition. As indicated by these chapter headings, the book covers almost all of the main divisions of protein chemistry. The subject matter, as well as the extensive bibliographies at the end of each section, should be of great value in stimulating further work in this important field. This volume will be found interesting and useful not only by students of protein chemistry but by all others interested in obtaining a better understanding of the part played by amino acids and proteins in life processes.

**Krankheiten und Hygiene der warmen Länder. Ein Lehrbuch für die Praxis.** Von Prof. Dr. P. Mühlens, Prof. Dr. E. Nauck, Doz. Dr. H. Vogel und Flottenarzt Prof. Dr. H. Ruge. Fourth edition. Paper. Price 43 marks. Pp 564 with 438 illustrations. Leipzig: Georg Thieme 1938.

This revised and enlarged edition of the standard German manual on tropical medicine and hygiene is especially welcomed, since the third edition (1930) has long been out of print. It also constitutes a posthumous tribute to Professor Reinhold Ruge, who died in 1936 during the preparation of the new edition. Drs. Nauck and Vogel are new collaborators, whose original contributions respectively in tropical pathology and helminthology entitle them to write with considerable authority. Prof. Erich Martini has taken over the sections on venomous animals and arthropods.

The volume is divided into nine sections in addition to a preliminary chapter on tropical hygiene and one on examination of the blood, both of which were written by Professor Ruge. Section I is entitled "Infektionskrankheiten" and contains a long chapter on malaria (Mühlens, Nauck) and shorter chapters on diseases due to trypanosomes (Ruge), leishmaniasis (Mühlens), amebic dysentery (Mühlens), spirochetosis (Mühlens) and virus diseases, Rickettsia infections and Bartonella infections (Nauck). Section II deals with deficiency diseases (Nauck) and section III with bacterial infections (Ruge). Section IV presents the subject of helminthiasis (Vogel) and diseases caused by arthropods (Martini). Section V is devoted to a consideration of dermatology and venereal diseases (Ruge). Section VI presents information on venenation due to animals (Martini) and to plants (Ruge). Section VII presents other tropical diseases (Ruge), section VIII, surgery in the tropics and section IX,

distribution of the principal cosmopolitan diseases in the tropics (Ruge). There is a rather complete subject index but an author index is lacking.

The chapter on tropical hygiene is a well balanced, compact consideration of the essential extrinsic and intrinsic factors governing man's life being in tropical lands. The chapter on blood is a brief syllabus on the origin and differential characters of the blood cells, preparation of blood for total and differential counts, hemoglobin index, hemoglobin mass and other laboratory analyses.

In the chapter on malaria Professor Mühlens describes in considerable detail the human and mosquito phases of the life cycle, including information on the structure and habits of the more important malarial transmitters. Epidemiology and pathologic anatomy of the disease are briefly presented and the symptomatology and diagnosis techniques authoritatively reviewed. In the extensive consideration of therapeutics there is detailed information on the administration of quinine plasmochin and atabrine, together with their respective efficiencies in tertian, quartan and estivo tertian malaria. Therapeutic prophylaxis and symptomatic therapeutics supplement this important part of the chapter. The preventive phase of the subject presents especially the problem of drainage, Paris green and oil treatment of water as larvicidal methods, screening and educational campaigns as necessary intrinsic attacks on the parasite. Included in this chapter are also a comprehensive discussion of black-water fever and a brief consideration of malaria in the monkey.

In similar thorough fashion although in somewhat briefer form there are considered trypanosomiasis and Chagas' disease, visceral, cutaneous and mucocutaneous leishmaniasis, amebic dysentery with the complication of liver abscess, balantidial dysentery and flagellate infections of the bowel, louse borne and tick-borne relapsing fever, various infectious rickettsiae (Weil's disease), yellow fever, dengue, paratyphoid fever, typhus, Rocky Mountain spotted fever, Japanese fever, verruga peruana, smallpox and psittacosis.

The deficiency diseases of sprue, beriberi, pellagra and related clinical entities are probably given too little consideration, but the bacterial diseases of bacillary dysentery, undulant fever, cholera, tularemia and plague are adequately presented.

The section on parasitic worms is prefaced by a few paragraphs on orientation and on consideration of techniques for recovery of helminth ova. These infections include the three types of schistosomiasis, pulmonary distomatiasis, hepatic and intestinal distomatiasis, tapeworm infections, hookworm disease, ascariasis, strongyloidiasis, whipworm infection and an especially valuable consideration of the filarial infections and dracunculosis. Entirely too little space is devoted to arthropods of medical importance.

In the section on cutaneous and venereal diseases of the tropics are to be found a full consideration of leprosy and of granuloma inguinale and briefer reference to the mycoses and the poorly understood malformation of the cutaneous, osseous and cartilaginous structures. Among the venereating animals are brief references to coelenterates, chilopods, scorpions, spiders, scabie mites, ticks and venomous insects, stinging fishes, and a more extensive treatment of poisonous snakes. In the short section on other tropical diseases are found tropical macrocytic anemia, sickle-cell anemia and tropical splenomegaly. The sections on surgery in the tropics and cosmopolitan diseases in the tropics have apparently been added for the sake of completeness, but they detract rather than add to the value of the volume.

In an attempt to evaluate as well known and as important a manual as is the present contribution from the Hamburg school, one is first struck with the painstaking, thorough way in which the subject of human diseases in the tropics has been presented and the accurate, authoritative information which is found in almost every chapter. Only in one respect is the subject as a whole possibly subject to criticism, namely the lack of balance in the presentation of the subject matter. A chapter entitled "Amebic Dysentery" would more appropriately have been entitled "Amebiasis," since it includes a consideration not only of acute (i.e. dysenteric) cases but also of subacute, chronic and carrier states, as well as amebiasis of the liver and other organs. The volume is splendidly printed and has an abundance of well selected line drawings, charts, photographs and photomicrographs.

**Nutrition in Health and Disease** By Ienna F. Cooper, B.S., M.A., M.H.F., Chief, Department of Nutrition, Montefiore Hospital, New York City; Edith M. Harber, B.S., M.S., Lecturer on History of Cookery, Teachers College, Columbia University, New York; and Helen S. Mitchell, B.A., Ph.D., Research Professor of Nutrition, Home Economics Division, Massachusetts State College, Amherst, Massachusetts. Seventh edition. Cloth. Price \$3.10. Pp. 704 with 101 illustrations. Philadelphia, Lippincott & London, J. B. Lippincott Company, 1938.

The appearance of a seventh and greatly revised edition, within ten years after the original publication, bespeaks the popularity of this textbook on the principles of nutrition and practice of dietetics for nurses. The subject matter is intended to be covered in two courses, the one on the principles of nutrition and cookery and the other on diet in disease. Each chapter concludes with a list of questions the correct answers to which will serve as a summary and review. The last fifty pages of the book provide in tabular form information regarding the composition of foods and other useful information. There is also provided a concise description of procedures concerned with the management of diabetes, such as tests for sugar and acetoacetic acid in the urine and the technique of administering insulin. There is no discussion of prothrombin, zinc, insulin, however.

There are numerous illustrations and many tables throughout the text. A valuable feature is the large number of recipes, covering nearly a hundred pages and providing detailed instructions for the preparation of small amounts of foods, usually one serving. Following the directions for each dish there is a table of ingredients. This shows the amount of each ingredient in terms both of common measures and of approximate weight in grams. The amount of protein, carbohydrate and fat that each ingredient provides is also listed together with the number of calories. The text has a suitable index. Any person who masters the contents of this book would have a sound knowledge of the principles of nutrition and dietetics.

**Sammlung psychiatrischer und neurologischer Einzeldarstellungen** Herausgegeben von Prof. Dr. A. Bostroem und Prof. Dr. J. Lange. Band VII. Die Psychologie und Psychopathologie der Hysterie. Von Dr. Robert Einker. Paper. Price 4.20 marks. Pp. 63. Leipzig, Georg Thieme, 1935.

The author reviews the current theories of hysteria and points out the flaws in each. He then postulates his own thesis that hysteria is a disturbance of "goal oriented activity." This peculiar concept is a descriptive pronouncement which does not further our knowledge of the dynamics of hysteria and its origin. His therapy consists in educational methods during childhood to strengthen goal seeking activity. He is not sure that therapy is possible for adults.

**The Chemical Analysis of Foods and Food Products** By Morris B. Jacobs, Ph.D., Chemist, Bureau of Food and Drugs, Department of Health, City of New York, 1928. Cloth. Price \$6. Pp. 537 with 56 illustrations. New York, D. Van Nostrand Company, Inc., 1938.

Methods of food analysis have been developed in order to obtain information about the composition of foods for nutritional and dietetic purposes, to aid in the standardization of production and manufacture of products, and for regulatory purposes to protect the people against deleterious, harmful or adulterated foods. This book was written to give a "systematic coverage to the salient facts of the chemical analysis of foods and food products." There is first a discussion of general methods and physicochemical methods of analysis, followed by chapters on coloring matters, preservatives and metals in foods. There follow separate chapters on various classes of foods, including milk and cream, milk products, oils and fats, sugar foods and carbohydrates, gums, cereals, starch and other polysaccharides, jams, jellies and fruit, spices, flavors and condiments, non-alcoholic beverages and allied products, alcoholic beverages, meat, meat products, fish and eggs, vitamins and inorganic determinations. Many of the methods of analysis described are taken from the description of methods of the Association of Official Agricultural Chemists, often without proper credit being given.

From the nutritional point of view this volume as well as many other volumes on food analysis, is somewhat disappointing. For example, there is described by the present author the method for determining the alkalinity of the ash of foods by titration of the ash. It was shown by H. C. Sherman more than thirty years ago that this method is inadequate and gives

misleading or inaccurate information. There is no point in retaining this now outmoded technique of determining the alkalinity of the ash of foods.

The author seems somewhat unfair in criticizing the Association of Official Agricultural Chemists because it has not described as yet, in its official publications, several methods which the author points out are included in this book. It is well known that the Association of Official Agricultural Chemists is thoroughly abreast of the times in its studies of methods of analyzing food products. The association publishes official methods only after they have been given thorough study and found suitable.

While the present author describes several methods for the determination of lead in foods, only one method is described for copper. The carbamate method, which is probably used more than any other for the determination of the small traces of copper that occur in foods, is not described. There may be a description of a method for the determination of the iron content of foods in the book, but the reviewer was unable to find it though he searched particularly. The word "iron" does not appear in the index. In a book which purports to be a collection of modern methods, one would think that there would be a description of a suitable method for the determination of iron, possibly even a method for the determination of inorganic iron.

The author describes in considerable detail of procedure for the detection and determination of milk solids in bread. This involves the analysis of bread for lactose and butter fat. It is realized, of course, that a useful procedure of food analysis is to identify a substance by selecting some characteristic ingredient which can be readily determined. There is justification, therefore, for a method of estimating the amount of milk solids in a food by determination of lactose and butter fat. From the nutritional point of view, however, the chief value of adding milk to bread is the improvement in the protein and calcium content of the bread. It would seem therefore that a calcium determination, possibly in conjunction with the analysis of lactose, would give more useful information than the determination of the lactose and butter fat. But then the book does not describe a method for calcium.

The book despite its imperfections should prove to be a useful volume to all persons concerned with the analysis of foods and food products.

**Pneumococcus Types in South Africa. A Study of Their Occurrence and Distribution in the Population and the Effect Thereon of Prophylactic Inoculation.** By David Ordman B.A. M.B. Ch.B. The South African Institute for Medical Research, Johannesburg. Publications of the South African Institute for Medical Research No. XLIII Vol. IV. Edited by the Director. Paper. Pp. 27 with 10 illustrations. Johannesburg: The Institute. 1938.

This little pamphlet contains some interesting information concerning the investigations on pneumonia which have been under way in South Africa for a number of years. In 1913 Lister reported, independently of Dochez and Gillespie, a biologic classification of pneumococci based on bacteriologic studies of pneumonia among the mine workers of South Africa. The various types were designated by the letters of the alphabet, A, B, C and so on. In this report Ordman correlates the South African alphabetical types with the American numerical types and generously consents to use the American classification in all future reports. It is interesting to note that in South Africa pneumococcus types I, II and III are the dominant types just as they are in America and Europe. Types V, VII, VIII and XIV are also fairly common in South Africa. A polyvalent pneumococcus vaccine containing types I, II, III, V, VII, XII and XIV was employed by Ordman for vaccinating the natives who were working in the mines. The vaccine caused a 75 per cent reduction in the incidence of type I pneumonia and a 42 per cent reduction in the incidence of type II pneumonia. The incidence of type III pneumonia was not affected by the vaccine.

**Bouquets of Rhyme. Variegated Nuances of Lyrical Diapason.** By O. E. Harvey M.D. Cloth. Price \$2. Pp. 96. New York: Aron House Publishers. 1938.

This collection of poems written by a busy practitioner constitutes a creditable amateur literary effort. Although there is considerable variation in quality, the author may be congratulated on his initial contribution in this difficult field.

**The Fundamentals of Internal Medicine.** By Wallace Mason Yater A.B. M.D. M.S. Professor of Medicine and Director of the Department of Medicine, Georgetown University School of Medicine, Washington D.C. Cloth. Price \$9. Pp. 1021 with 255 illustrations. New York & London: D. Appleton Century Company, Incorporated. 1938.

This volume differs from most other textbooks of medicine in its condensed discussions and in the fact that it includes material on diseases of the skin, ear, eye and other specialties which the author and his collaborators believe to constitute a necessary minimum of the knowledge of the internist or general practitioner. The book is excellently illustrated. While many details have been sacrificed to simplification and space requirements, it may be anticipated that the book will be popular with medical students and many practitioners.

**Praxis der Tuberkulosekrankheit und ihrer Behandlung.** Herausgegeben von Dr. med. habil. Hellmuth Delst, Oberstabsarzt der Heilstätte Übereuth im Allgäu. Mit einem Geleitwort von Prof. Dr. O. Müller. Paper. Price 16 marks. Pp. 212 with 90 illustrations. Leipzig: Johann Ambrosius Barth. 1938.

The first part of this volume contains a general consideration of tuberculosis. There is a good discussion of the diagnosis, prognosis and treatment. Under treatment the various special procedures, such as artificial pneumothorax and intrapleural pneumonolysis, are discussed at considerable length. Various complications in pulmonary tuberculosis are considered. Nearly fifty pages is devoted to tuberculosis in children, in which the evolution of the disease is presented. Most of the illustrations are made from roentgenograms. Unfortunately, this volume does not contain a bibliography.

**Introduction to Diseases of the Chest.** By James Maxwell M.D. F.R.C.P. Assistant Physician and Demonstrator of Practical Medicine, St. Bartholomew's Hospital, London. Cloth. Price 12s. 6d. Pp. 328 with 95 illustrations. London: Hodder & Stoughton Limited. 1938.

This is an elementary discussion of diseases of the chest. It is written for the medical student and makes no attempt to discuss rare or obscure topics. As is usual in books on this subject, considerable space is devoted to physical diagnosis and history taking. The text deals almost entirely with the clinical aspects of the subject, probably too much so for the average medical student. Even suitable prescriptions for cough mixtures are included. The sections on history and physical examination are followed by one on special investigations. This includes sputum, blood, pleural fluid and an excellent chapter on radiology of the chest. The section on diseases of the respiratory tract commences with chapters on the diseases of the nose, mouth and larynx. Chapters on each of the important diseases of the bronchi, lungs, pleura, mediastinum and diaphragm follow. The clinical descriptions are, in general, excellent. Reproductions of roentgenograms, of which there are a profusion, are well done and add much to a book on this subject. The chief criticism of this book is with regard to therapy. Frequently a number of methods of treatment are mentioned without any discussion of the merits of each. In the important chapter on lobar pneumonia, only a small paragraph at the end is devoted to specific serum therapy. The author states that "it is doubtful whether, in the average case, anything is to be gained by giving serum." In this and in certain other instances the text is not thoroughly abreast of the time. As a whole, however, this book can be recommended as a sound clinical discussion of the subject.

**Le traitement des rigidités extra pyramidales par la médication belladonna à hautes doses.** Par le Docteur Jean Roux Delimal. Paper. Pp. 79. Paris: Librairie E. Le François. 1938.

The author introduces the subject by discussion of the Solanaceae and their alkaloids and especially the acids and bases found in belladonna. He emphasizes particularly the preparation of the wine of belladonna according to Raef's method, which has been used in the Bulgarian treatment so highly considered in Italy. The method of using belladonna and atropine is also discussed, together with the dangers and the accidents that sometimes occur, the tolerance to the drug and, finally, the therapeutic results. The high tolerance for atropine in parkinsonism (20 mg. or more) is particularly stressed. The author contends that the so called Bulgarian treatment, which is the wine of belladonna combined with what appear to be charcoal pills, laxative and chewing gum, is distinctly favored over atropine itself. The author points out that extrapyramidal disorders accompanied by hypertonus

are particularly benefited, while those of pyramidal type are, if anything, made worse. The mechanism of action is discussed. As an exposition of a practical method of treating extrapyramidal hypertonus this Paris thesis has some value, but it cannot be considered adequate on account of the lack of discussion of other drugs that have been found useful in this condition and for the very inadequate study of the mechanism of the effects.

**Statistical Methods Applied to Experiments in Agriculture and Biology**  
By George W. Snedecor, Director of the Statistical Laboratory of Iowa State College, Ames, Iowa. Second edition. Cloth. Price \$3.75. 1935. 184 pp. Ames, Iowa: Collegiate Press, Inc. 1935.

There seem to be no remarkable changes in this revision of a book issued originally in 1937. It is claimed to be suitable for those without a knowledge of higher mathematics, but most physicians would find it rather heavy going.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Birth Control Contraceptive Articles as Articles of Indecent or Immoral Use, Contraception as Against Public Policy**—Lantec Laboratories, Inc., was engaged in the sale of devices and preparations for the prevention of conception. Its president undertook to design and perfect a universally adaptable contraceptive diaphragm that could be marketed through drug stores. The defendant and his brother were employed to aid in the development of such a diaphragm. Their contract of employment provided that any applications for patents for articles covered by the contract, filed by the defendant or his brother during the life of the contract or five years thereafter, should be assigned to the plaintiff corporation on its request. The contract terminated about Aug. 1, 1931. Thereafter, on Nov. 2, 1935, the defendant filed an application for a patent for "a pessary or vaginal diaphragm and an applicator therefor." The plaintiff contended that the application covered an invention to which it was entitled under the contract and instituted an action to compel the inventor to assign the application to it. The trial court dismissed the complaint, holding that the application did not come within the terms of the contract. The plaintiff corporation thereupon appealed to the appellate court of Illinois, first district, second division.

Although the record from the trial court raised no question as to whether the contract was not against public policy and therefore void, the appellate court on its own motion discussed that aspect of the case at length and apparently gave weight to its conclusion with respect thereto, in rendering judgment. The subject matter of the contract, said the court, was the invention of a contraceptive device that any woman could obtain without consulting a physician or a clinic, the invention of an article that could be sold through drug stores to any woman, married or single, who called for it. No direction or prescription from a physician would be required, to show that the article was to be used for the cure or prevention of disease. The plaintiff's brief frankly stated that the nature of the device and the manner in which it was to be sold would enable a woman to obtain the article as she would "medical and personal supplies, over the counter."

The national policy of the United States with respect to the matter of contraception, the court pointed out, is clear. The federal criminal code provides that every article or thing designed, adapted or intended for preventing conception or for any indecent or immoral use, and every article, instrument, substance, drug, medicine or thing which is advertised or described in a manner calculated to lead another to use or apply it for preventing conception, is not admissible to the mails. This prohibition has been on the statute books for sixty-five years, the court continued, and despite repeated efforts to have the law amended or modified, Congress has refused to change it. Furthermore, the tariff act of 1930 prohibits the importation of any article whatsoever for the prevention of con-

ception. It is true that a federal court has held that the tariff act does not bar from the country articles employed by physicians in the practice of their profession, for the prevention of conception, when necessary to protect the patients' health or to save them from infection. *United States v. One Package*, 86 F. (2d) 737. But, the Illinois appellate court pointed out, in rendering that decision the United States circuit court of appeals conceded that it departed from the letter of the law. And although the Illinois appellate court recognized that it had been held that in a prosecution under the federal criminal code for mailing an article for contraceptive purposes it is necessary to prove not only that the article mailed was designed and adapted for contraceptive purposes but to prove also that it was intended for preventing conception, the Illinois court nevertheless pointed out that the public policy of the United States, as expressed in the statute governing the matter, has not been changed by Congress.

The criminal code of Illinois declares illegal the sale of any model, cast, instrument or article of indecent or immoral use. While no mention is made in the code specifically of articles to prevent conception, it does include "any instrument or article of indecent or immoral use." The federal criminal code the court pointed out, places contraceptive devices in the class of articles for "indecent or immoral use." It has frequently been held that the purpose of the federal statute was to exclude from the mails publications and articles deemed injurious to public morals.

In view of the subject matter of the contract before the court in the present case and of the manner in which the contraceptive device that forms the subject matter of the contract was to be sold, it seems clear, said the Illinois appellate court, that if a person were to use the mails to deliver the contraceptive device in question to drug stores, to be sold in the manner planned by the plaintiff, he would be guilty under the criminal code of the United States. He would also be guilty under the criminal code of Illinois, that code being broad enough to cover the indiscriminate sale of contraceptive devices through drug stores. It certainly could not be reasonably contended, the court thought, that sales so made might not tend to corrupt the morals of young unmarried persons. Would not the indiscriminate sale of contraceptive devices to such persons, the court asked, constitute the sale of an "article of indecent or immoral use?"

The maxim that he who comes into equity must come with clean hands, said the court, is of ancient origin and broad application. It is the expression of the elementary and fundamental conception of equity jurisprudence. An analogous situation was presented in the present case, in the opinion of the appellate court, when equity opened its door to settle the dispute between these "sordid traffickers in contraceptives." Without passing, however, on the validity of the contract in its relation to public policy, the appellate court contented itself with affirming the judgment of the trial court in favor of the defendant, which reached the conclusion that the contract between the parties did not cover the device for which the defendant filed an application for a patent.—*Lantec Laboratories, Inc. v. Clark (Ill.)*, 13 N. E. (2d) 678.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Medicolegal Aspect of Carbon Monoxide Poisoning**—Beck divides carbon monoxide poisoning into three groups: acute asphyxiation, acute asphyxiation with delayed or secondary symptoms and chronic poisoning. From a medicolegal standpoint the first group does not present a difficult problem, as death resulting from acute asphyxiation is either accidental or suicidal. The second and third groups arouse much controversy in adjusting claims for disability. In the second group the patient apparently recovers from acute asphyxiation, but in the course of several days to a week acute symptoms often of a severe character will develop, usually referable to the central nervous system or the heart. These cases ultimately manifest symptoms of encephalitis or other organic cerebral lesions or coronary thrombosis and myocardial insufficiency due to lesions caused by the anoxemia. The patients may die during the early stages of the sequels of acute poisoning or they may recover sufficiently to resume their accustomed occupation. Unfortunately, in the course of such a sequence of events carbon monoxide in its etiologic relations may be easily overlooked and the illness is ascribed to other causes. Thus, only by a careful history and a thorough knowledge of the underlying pathologic processes associated with anoxemia can the significance of carbon monoxide be ascertained definitely as a contributing factor. Many persons who live in houses or work in offices heated by open gas heaters without ventilating flues, or drive in closed automobiles with defective engines and exhausts, suffer from the daily exposure to sublethal or mildly noxious quantities of the gas. This constitutes the third group. The most familiar symptoms are those due to mere oxygen want. Even the milder forms of chronic carbon monoxide poisoning are subject to the same complications and sequelae as those occurring in acute asphyxiation. The symptoms and after-effects of a given blood saturation will be more severe if there has been a long exposure to a low concentration than if there has been a short exposure to a high concentration. When these facts become generally recognized by the profession, legal experts should have less difficulty in procuring workmen's compensation for disability incurred from carbon monoxide, especially after recovery from acute asphyxiation. The chapter on carbon monoxide poisoning in its relation to industrial medicine must be revised so as to incorporate the recent knowledge gained through clinical observation and experimental studies. The tendency to cause death and disability from the remote effect of acute poisoning and the chronic effect of slow but persistent poisoning must be more generally recognized. Not until this view is accepted by the profession and offered as testimony can industrial commissions or courts be expected to render just decisions for compensation.

**Fleas as Vectors of Plague**—Eskey points out that of twenty different species of fleas infected with plague in the laboratory only eleven species, nine of which were collected from wild rodents, transmitted the disease to guinea pigs, only a portion of fleas fed on plague infected guinea pigs a few hours before the animals died were infected, and of those infected only a small percentage transmitted the plague to other guinea pigs. Flea bites are not infectious until the masses formed by *Pasteurella pestis* cause obstruction of the esophagus. This condition may develop in a few days or not for more than four months. Few fleas ever infect more than one animal and blocked, infectious fleas generally die within forty-eight hours of the time there is evidence of obstruction to their stomachs. Infected fleas are constantly excreting virulent coccobacilli in their feces, which may survive for as long as four weeks in the dried excreta so that rodents are exposed to infection from the feces as well as the bites of fleas. There is always a possibility of human beings contracting bubonic plague from blocked fleas present on wild rodents in regions in which sylvatic plague exists, but these fleas are not nearly so dangerous to man as the domestic rat fleas *Xenopsylla cheopis*.

**Focal Infection and Rheumatoid Arthritis**—In a study of 200 consecutive cases of rheumatoid arthritis, Cecil and Angevine found definite evidence of focal infection in 20 per cent and a questionable focus in 10 per cent. This is a great contrast to the high incidence of focal infection found in clinic patients ten years ago. Only nineteen patients had a history of an acute infection of the upper part of the respiratory tract such as coryza, pharyngitis or influenza preceding the onset of the arthritis. A smaller number of cases came on after psychic trauma, childbirth, puerperal fever, physical injury or operation. The tonsils had been removed in forty-six per cent of the cases because of arthritis, although only about 15 per cent gave any history of tonsillitis or sore throat. The operation had no effect on the course of the disease in eighty-six

cases, caused a severe exacerbation in two and temporary improvement in four. In no instance was the course of the disease arrested or the patient cured. In one instance the operation on infected tonsillar stumps appears to have been the precipitating cause of the onset of the arthritis. Because of arthritis fifty-two patients had had some, and in many instances all, of their teeth extracted. There was no benefit in forty-seven, and three patients reported a flare up of the pain in their joints following the extractions. Thirty patients gave a history of sinus disease and twelve had been treated for sinusitis before coming under the authors' observation. The treatment was of no benefit in ten and there was an exacerbation of the disease in two. When first seen by the authors, twenty-seven patients had an infection of the tonsils or remaining tonsillar stumps. Twenty of these patients were treated, thirteen remained unimproved or became worse and temporary improvement occurred in only seven. This improvement lasted from one week to several months. At the time of examination only eleven of the 200 patients gave evidence of an active sinus infection. Five of these cases were treated all without benefit. In the three cases in which additional dentistry was performed there was no benefit. The authors stress the fact that a more conservative attitude should prevail regarding the treatment of tonsils, teeth and sinuses in rheumatoid arthritis. A complete revision of the focal infection theory should be made. Undoubtedly there are cases of infectious arthritis which result from focal infection. However, as far as typical rheumatoid arthritis is concerned, chronic focal infection apparently plays a comparatively unimportant part.

**Liver Function in Hyperthyroidism.**—Bartels determined the hepatic function in 148 cases of clinical hyperthyroidism by the hippuric acid excretion test suggested by Quick. Seventy-eight patients had primary hyperthyroidism permitting a subtotal thyroidectomy, thirty-nine had primary hyperthyroidism requiring a two-stage operation, and thirty-one had adenomatous goiter with hyperthyroidism permitting a subtotal thyroidectomy. Hepatic function determinations were obtained on the day after admission, on the day prior to operation (from eight to fourteen days being taken for preoperative treatment) and on the sixth or seventh postoperative day. Tests were again performed on forty-two patients three months postoperatively when they returned for their metabolic check up. In the group of seventy-eight patients the average hippuric acid excretion on admission was found to be 2.3 Gm. The average admission basal metabolic rate was plus 36 per cent. Of the entire group only ten patients had determinations above the accepted normal of 3 Gm. After the usual preoperative period the average hippuric acid was 2.55 Gm and the average basal metabolism plus 22 per cent. Three months postoperatively the average basal metabolic rate was minus 3 per cent and the average hippuric acid excretion was 3.34 Gm, with 85 per cent of twenty patients now having normal excretions. In the group of thirty-nine patients the average basal metabolic rate was plus 54 per cent and the average hippuric acid excretion 1.88 Gm. Only one patient had a normal value for the hippuric acid excretion. Preoperatively to the first stage the basal metabolic rate fell to an average of plus 36 per cent and the average hippuric acid excretion increased to 2.33 Gm. Postoperatively a slight drop occurred in the average hippuric acid excretion. At the time of the second stage the average basal metabolic rate was plus 21 per cent with the average hippuric acid excretion 2.51 Gm. Postoperatively the average hippuric acid excretion was 2.66 Gm. At the three months check up the average basal metabolism was minus 7 per cent in sixteen patients with the average hippuric acid excretion 3.12 Gm, at which time 77 per cent had normal determinations. In the thirty-one cases of adenomatous goiter with hyperthyroidism the average basal metabolic rate on admission was plus 36 per cent and the average hippuric acid excretion 2.27 Gm (only seven normal). Postoperatively the hippuric acid excretion was 2.36 Gm, with 16 per cent of the cases being normal. At the three months check up an average metabolic rate of minus 5 per cent and a hippuric acid excretion of 3.34 Gm was obtained in six patients. A close relationship seems to exist between the level of the basal metabolism and the hippuric acid excretion. The duration of the hyperthyroidism

was not a potent factor in determining the degree of reduced hepatic function. Patients having acute hyperthyroidism were found to develop degrees of impairment of the liver in a few months, whereas patients with milder types showed little change even over a period of years. This observation is corroborated by the fact that, whereas the average duration of the disease in the group of cases of primary hyperthyroidism in which a subtotal thyroidectomy was done was ten months and in the group of adenomatous goiters twenty-one months, the hippuric acid excretion in these two groups was found to be the same. The absence of weight loss or a history of previous iodine administration was usually noted in conjunction with a normal hepatic function test on admission. No apparent relationship was demonstrated between the level of the liver function and the degree of postoperative pulse and temperature response. A close relationship was found to exist between the blood cholesterol and the hippuric acid excretion. The use of a high carbohydrate diet apparently improved hepatic function as indicated by increased hippuric acid excretion.

**Sterilization of Air in Operating Room.**—Hart analyzes the results obtained in a total of 456 clean primary incisions and eighty-six reopened clean incisions out of more than 800 operations performed in a field of bactericidal radiation. The other operations had a potential source of infection, and data on them were not used for the statistics. The operations were gastric or intestinal resections, cholecystectomies, appendectomies and amputations of gangrenous extremities. A striking improvement in the postoperative course of these patients has been evident. Unexplained infections in primary incisions have been almost, if not entirely, eliminated. More striking than this reduction in the number of infections has been the reduction in the elevation of temperature following operation and the shortening of the duration of this postoperative elevation. The postoperative course of the patients has been improved. They show less reaction in every way, there is less tenderness in the incision, and the period of convalescence is reduced. The author concludes that postoperative wound infections have been reduced more than 85 per cent. The occasional death from wound infection has been eliminated. The number of patients with a postoperative temperature above 100.4 F has been reduced in thoracoplasties from 68 to 30 per cent, in radical mastectomies from 46 to 34 per cent and in inguinal herniorrhaphies from 36 to 22 per cent. The number of patients with a temperature above 99.5 F for more than four days after operation has been decreased in thoracoplasties from 78 to 22 per cent, in radical mastectomies from 54 to 21 per cent and in inguinal herniorrhaphies from 46 to 14 per cent.

**New Surgical Mask.**—Arnold found that a craped wadding (cellucotton) made of wood cellulose is an efficient mask and air filter material. This material is more effective, as bacteria

are prone to adhere to it even after washing, than the cotton gauze generally used in surgical masks. The greatest source of oral bacterial flora in the experiments that he performed was escape or deflection of the expelled air during talking, above the mask laterally to and on each side of the nose. Covering the nose and mouth with an impermeable material deflects the expired air all round the edges of the mask, and the atmospheric pollution is the same as if no mask were worn. The problem is one of prevention of atmospheric pollution by filtration, similar to removal of bacterial pollution from water by filtration methods. The author feels that his experiments show the effectiveness of cellulocotton as an air filter. The next problem is to prevent air containing bacterial flora of the upper part of the respiratory tract from leaking round the edges of the mask. He is convinced that if all the expired air can be forced through the cellulose wadding filter the bacteria will remain on the cellulose fibers.

**Immunology of Hay Fever**—Langner and Kern confirm, by means of the intracutaneous passive transfer technic, the presence of an inhibiting substance (blocking or inhibiting antibody) in the serum of treated hay fever patients and report observations on the passive transfer of this inhibiting substance to untreated hay fever patients by means of "immune" serum that, for convenience of handling and preservation, has been lyophilized. Dried serum of hay fever patients treated with specific pollen extract was found to contain the blocking substance first described by Cooke and his associates. Treatment of patients with active hay fever by means of dried immune serum gave results sufficiently encouraging to warrant further application and refinement of this procedure as an additional method of treatment for selected cases of hay fever.

**Sighing Dyspnea**—Maytum declares that sighing respiration is a normal reaction to fatigue and mild emotional states, yet it is possible for sighing respiration to assume considerable

clinical importance and to produce a definite clinical syndrome. The condition is a functional disorder. This syndrome has not infrequently been mistaken for asthma and some patients with this syndrome have been submitted to extensive allergic investigation. In 1929 White and Hahn reported that it was a very rare symptom in heart disease and that when it was present it was not due to the heart disease but to nervous excitability. "Shortness of breath" or the inability to take a deep breath is the chief symptom of the patients. A feeling of constriction, tightness, weight or pain is usually present in the thorax, and palpitation is a frequent symptom. Fatigue and nervousness are common, and many of the patients have recently been subjected to some nervous shock or to cares and worries of considerable magnitude. Anxiety regarding their state of health is almost always present. Sighing dyspnea occurs more often among women than among men, and it usually occurs in the more active years of life. Sighing dyspnea is definitely a functional disorder of respiration and is not caused by organic disease. Treatment in these cases is based entirely on an adequate explanation to the patient of the underlying mechanism and the method by which attacks are produced. It should be explained as a normal reaction to fatigue and emotional stress. Sedatives may help to control existing nervous irritability. Hyperventilation tetany, if present, can be controlled in a few minutes by the administration of carbon dioxide. It is also helpful to demonstrate how easy it is for the patient to bring on an attack of tetany by voluntary overbreathing.

\*Comparative Study of Laughlin Test for Syphilis R O Muether and J E Greutter St Louis—p 212

**Cardiovascular Disease Without Hypertension**—Schwab and Curb subjected seven patients with established hypertensive cardiovascular disease whose blood pressure had fallen to normal or subnormal levels to the cold pressor test and observed the blood pressure response. In five instances the typical hypertensive type of response was obtained. This suggests that the application of such a procedure to patients of this type would materially aid in the clarification of the etiologic cardiac diagnosis.

**Leukocytosis**—Nettleship tested, in rabbits, two of the possible causes of leukocytosis: withdrawal of leukocytes from the blood stream or the presence of an irritant in the blood. The withdrawal of leukocytes, either by venipuncture or into an abscess area, cannot account for leukocytosis. In acute experiments silver nitrate injected intracutaneously cannot be found in the blood or internal organs. It is recovered in large amounts from the area of injection. Silver nitrate injected intracutaneously causes necrosis accompanied by a primary leukopenia followed by marked polymorphonuclear leukocytosis. Egg albumin injected into nonsensitized animals diffuses from the

injection site and causes a leukopenia. Injected into sensitized animals, egg albumin does not diffuse into the blood stream. Peripheral necrosis occurs with a concurrent well defined leukocytosis.

**Laughlin Test for Syphilis**—Muether and Greutter compared the efficiency of the Laughlin test for syphilis by performing this test and the Kahn and Kline tests on 1,000 serums. The Kahn test was the most accurate test in their hands, giving only one false positive reaction and two false negative reactions in 1,000 cases. The accuracy of the Laughlin test increased with experience. If 1,000 cases are divided into two groups it is found that nineteen, or about 80 per cent, of the false positive tests fall in the first 500 cases tested while eight or about 55.5 per cent, of false negatives occurred in the first 500 cases. These analyses of the cases, as two groups, strengthen the authors' belief that the Laughlin test is quite accurate in untreated cases but is more readily reversed by treatment than are other tests. The Laughlin test is a clean, quick and economical test, with a fairly definite end point. The ability to determine the strength of the reaction on the basis of a time factor rather than on a quantitative basis is a distinct advantage, as there seems to be little reason to report any serologic test for syphilis by a series of plus signs. The test for syphilis is far better reported as negative, positive or doubtful. The Laughlin test requires a certain skill and training and it is not a test to be used casually in general practice. It might well be used by the large laboratories in which suitable controls can and will be done frequently.

**Vesical Bilharziasis**—Campbell discusses the bilharzial involvement of the lower part of the urinary tract and reports a case of approximately twenty years' duration. In spite of the extensive involvement of the bladder and lower part of the right ureter, and long duration of the disease, remarkable results were obtained with the use of two courses of intravenous fuadin.

**Effect of Hormones on Prostate**—Moore and McLellan studied microscopically the response on surgically enucleated prostatic tissue in ten presenile men, five after the injection of an androgen and five after the injection of an estrogen. The

testosterone propionate and the theclol benzoate were injected intramuscularly. Testosterone propionate, in from 285 to 1,125 mg doses for from twelve to ninety five days, the dose employed, had no significant effect on the prostatic epithelium or stroma. The failure to avert the physiologic process of senile involution by endocrine therapy indicates that senile involution of the prostate is not solely the result of diminution in secretion of androgens but involves a more complicated process, the nature of which must await further investigation. It is also possible that senile involution is an irreversible process. Either of these assumptions is valid despite the fact that the morphologic appearance of the prostate in senility and after castration is similar. The injection of from 15,000 to 140,000 international units of theclol benzoate in from ten to thirty-one days produced conspicuous alteration in the urethral and ductal epithelium but little if any change in the tissues of blem hypertrophy. As a basis for future work, an estrogen results in an exaggeration in the prostate of some of the most characteristic microscopic changes associated with benign hypertrophy: metaplasia and hyperplasia of the epithelium of the ducts and hypertrophy of the lymphoid tissue. On the negative side there is no evidence of the new formation of nodules and no evidence of the active growth of the formed nodules. The observed migration of leukocytes through the urethral and ductal epithelium after injections of an estrogen opens a new approach to the much disputed problem of chronic prostatitis. It may be that some of the cases of so called chronic prostatitis are the result of altered hormone states in which there is estrogenic preponderance.

**Ascorbic Acid in Whooping Cough**—Vermillion and Stafford used ascorbic acid in the treatment of twenty six cases of whooping cough confirmed in most instances by a high leukocytosis and lymphocytosis. The first sixteen patients were given 15 mg tablets of ascorbic acid, ten tablets daily the first three days, eight tablets daily the next three days and six daily until symptoms subsided entirely. The medication seemed to be strikingly effective in relieving and checking the symptoms in all but two of the patients, who apparently received little if any relief. The authors' opinion is that ascorbic acid should be given further trial in all cases of whooping cough regardless of the age of the patient or the length of time already elapsed since the original symptoms.

### Maine Medical Journal, Portland

20 235 260 (Nov.) 1938

- \*Metropathia Haemorrhagica F. Albright, Boston—p. 235  
Painful Conditions of the Heel E. M. Tower, Waterville—p. 239

**Hemorrhagic Metropathia**—Albright stresses the fact that in the treatment of hemorrhagic metropathia emphasis should be placed on nonspecific therapy. The condition generally develops in the run down individual. Iron therapy should usually be employed, as anemia predisposes to the condition and the condition leads to an anemia. Attention to diet and general hygiene are most important. Underlying conditions such as foci of infection and tuberculosis should be looked for. Until more is known, massive doses of vitamins are justified. Radical therapy is not necessary. The alternative may be a drawn out and tedious affair, but the condition finally clears up in most of these patients. In most cases it is desirable to perform at least one curettage to confirm the diagnosis and to rule out uterine cancer. The periodic administration of progestin is a simple method of producing periodic menstruation and preventing endometrial hyperplasia until such time as the underlying disturbance in the ovarian cycle is corrected. It is not the purpose to correct the underlying trouble with this pro-

cedure but merely to take care of one of its complications. In carrying out this treatment at the Ovarian Dysfunction Clinic, the author has given in the neighborhood of 5 mg. of progesterone in oil intramuscularly daily for six days every six weeks. Gonadotropic substance often causes cessation of bleeding in hemorrhagic metropathia and not too infrequently completely corrects the condition. The follicle stimulating hormone either alone or with the gonadotropic substance can be tried in an effort to produce a corpus luteum.

**Sulfanilamide in Pneumonia and Meningitis**—Sadusk reports two fatal cases of type III pneumococcus meningitis treated with sulfanilamide. The blood cultures in both were positive but became sterile following sulfanilamide therapy, although both patients died. In one case the spinal fluid also became sterile. Nine patients of 53 years of age or more, save one who was 18 with type III pneumococcus pneumonia, were treated with sulfanilamide. All the nine patients recovered and were discharged from the hospital in good condition. The further use of sulfanilamide in type III pneumococcus infections, until more data can be obtained for analysis, is suggested.

**Rocky Mountain Spotted Fever**—Pons and his associates cite seven cases of Rocky Mountain spotted fever from Monmouth County. All the patients contracted the infection in the locality. Six additional cases in which Rocky Mountain spotted fever was suspected were eliminated on the basis of a single negative Weil-Felix reaction. There is reason to believe that with repeated agglutination tests and animal inoculations the diagnosis of the disease might have been confirmed in some. Unless the clinicians become thoroughly familiar with the disease and insist on more corroborative laboratory data, cases of typhus and Rocky Mountain spotted fever are going to be misdiagnosed. As in typhoid, the agglutination test may be positive in the absence of infection, and conversely it may be negative in the presence of infection. Rocky Mountain spotted fever is such a clearcut clinical entity that the diagnosis on purely clinical manifestations is justifiable under some circumstances.

Management of Complicated Fractures of the Forearm W B Owen Louisville Ky—p 554

**The Adrenals in Adrenal-Genital Syndromes**—For the differential diagnosis between adrenal-genital syndromes with and without tumors, Cahill presents a method of visualizing the adrenal by x-ray. He uses a modified method of Carelli. With the patient on his side and a pillow under the opposite flank, the upper flank is sterilized. An area below the twelfth rib and between the outer border of the erector spinae muscle and the reflection of the peritoneum is injected with a dermal bleb of procaine hydrochloride and the subcutaneous tract is injected. A lumbar puncture needle is then introduced and as it passes through the transversalis fascia a change of resistance is noted and it enters the perirenal fascia. The needle is aspirated to assure avoidance of a blood vessel and is then attached to a sterile tube with a sterile cotton filter and an inflatable rubber bag. From 250 and 500 cc of air is slowly forced by hand through the cotton and needle into the perirenal fascia. A deep sense of fullness by the patient in the flank is assurance that the proper planes have been reached. A roentgenogram is taken and the air is localized. It may be displaced upward by manual pressure or by a rowing motion as described by Mencher. The air slowly diffuses, and series of roentgenograms are taken for twenty-four hours. The air may pass up through the mediastinum to the neck or may descend down the psoas to the thigh, and it takes from six to ten days to absorb. The value of such a procedure can be estimated only after its use in a considerable number of cases. Of fifty-seven cases of either adrenal cortical tumor or of the adrenal-genital syndrome, bilateral "airograms" were taken in fifty-five. The procedure has also been used in other adrenal conditions and for various obscure renal and abdominal conditions in more than 130 cases. Of the fifty-five cases in which airograms were taken there were seven males and forty-eight females. Among the seven males was an adult without demonstrable endocrine symptoms who showed a rounded shadow in front of the left kidney and apparently connected with the lower end of a long thin adrenal. The tumors causing these shadows were confirmed at operation. There were two children both with *macrogenitosomia praecox*,

average figure is from five to six times lower than that of normal subjects and every patient in whom active epidemic dropsy was diagnosed showed this lowered output. The urinary output of chlorides was also definitely lower in these patients. Obviously the patients are retaining a portion of the ingested salt, as many of the patients were taking the same diet as they had taken before they were attacked by this disease. The retention of chlorides is further proved by the fact that the concentration of chlorides in blood was increased during an attack of the disease. It is advisable, therefore, to decrease the amount of salt taken with the diet, in cases of epidemic dropsy. In the two cases in which the calcium excretions were examined they were found to be 225 and 172 mg per hundred cubic centimeters of the urine respectively. These values are small even when compared with the lowest values (61 mg) recorded for normal Bengalee subjects.

Methods of Estimating Intelligence and Personality and Their Applications J. M. Blackburn—p. 1008

**Cardiac Complications from Metrazol**—In the course of using metrazol in the treatment of twenty nine cases of mental disorders Dick and McAdam observed auricular fibrillation in three and temporary heart block in one. However all the patients treated had healthy hearts at the beginning of treatment.

**Mechanism of Metrazol Convulsion**—From their experimental results on thirty-two patients undergoing or about to undergo metrazol convulsions, it appears to Denysen and Watterson that the effects of metrazol on the circulation occur solely through the vasomotor center. The chief of these effects is vasoconstriction. Experiments with amyl nitrite and histamine demonstrate that vasodilatation antagonizes the action of metrazol, as under appropriate conditions it prevents the convulsion from occurring. The conclusion is that the convulsion itself is due to a vascular spasm.

**Gonococcic Endocarditis**—After reviewing the literature on gonococcic endocarditis, Gelbfisz and Zera discuss the localization and the pathologic anatomy. Then they report the clinical histories of two cases. In both of these the acute endocarditis coincided with gonococic urethritis, but the gonococic endocarditis was at no time accompanied by articular symptoms. These facts seem to be in disagreement with the opinion that arthropathy is the most frequent complication of gonorrhea. In both cases the intermittent type of temperature was maintained throughout the entire duration of the disease, and the disorder had a malignant aspect with an acute and rapid course, it resisted all attempts at treatment. The symptoms of the endocardial localization appeared in the two patients only during the last period of the disease. The valvular lesions consisted of characteristic polypous vegetations. Taking into consideration their own observations and those reported by others, the authors stress the following points: 1 In the course of gonorrhea, cardiovascular complications may develop which, if localized in the heart, usually attack the valves (gonococcic endocarditis). Involvement of the myocardium and of the pericardium is rare. 2 The endocardial manifestations may develop unexpectedly in the course of articular attacks or in the absence of articular complications. 3 Their course is usually malignant and becomes manifest in a grave septicemic syndrome with fatal evolution. More rarely the evolution is benign and results in chronic valvular defects. 4 The anatomopathologic lesions observed most frequently by all authors are polypous proliferations on the endocardium (polypous endocarditis). 5 The ages of the patients differ greatly (from 19 to 65 years). 6 The time which elapses between the gonococcic infection and the appearance of the endocarditis varies between three weeks and fourteen years. 7 The evolution of gonococcic endocarditis extends over a period of from ten days to thirteen weeks, but one author (Kawachi) observed a case which lasted two years. The authors emphasize that, in cases of endocarditis of obscure origin, gonococcic endocarditis should be thought of.

- Treatment of Adnexitis by Anesthetic Blockage C. Daniel—p. 71  
\* Prophylactic Treatment of Urinary Lithiasis E. Tant—p. 74  
\* Investigations on Fixation of Gonadotropic Hormones in Serum of Normal Pregnant Women and in Those with Hyperemesis G. Iegrand—p. 84

**Prophylactic Treatment of Urinary Lithiasis**—Tant shows that in order to arrive at an effective prophylactic treatment of urinary lithiasis it is necessary to take into account the three chief causes of this disorder. The first of these is the deposit of an excess of urinary substances. This excess can be provoked by foods or else it may be due to a defective metabolism. The second cause is the excessive precipitation in the urine under the influence of the urinary  $pH$ . The third cause is local and is probably associated with a chronic irritation of the urinary passages which provokes the crystalline precipitation and the formation of calculous concretions. In view of these three causal factors, the prophylactic treatment must aim to diminish the excessive urinary deposits, it must bring the urinary  $pH$  into a zone where precipitations cannot be produced and it must dissolve and eliminate the uric acid that has been retained in the organism. To reduce excessive urinary deposits, it is necessary to avoid certain foods. The author gives tables indicating the purine and oxalic acid contents of various foods. He then lists the foods that may be taken and those which have to be avoided by patients who are

subject to the formation of urinary calculi. Regarding the role assumed by the  $pH$  of the urine in the formation of urinary calculi, he says that uric acid precipitates in the urine when the  $pH$  is below 5.7. For this reason it is important for persons with a tendency to urinary lithiasis that the  $pH$  of their urine is always kept above 5.7. A vegetarian diet has a tendency to raise the  $pH$ . However, if the  $pH$  values rise above 6.6 or 6.8, phosphatic calculi may be formed. This shows clearly that the  $pH$  of the urine of patients with lithiasis must be kept under constant control. The dietetic restrictions alone are not sufficient; they must be complemented by other hygienic measures such as exercise in the open air. Violent exercises and physical fatigue should be prevented, however. Rest and meals should be taken at regular hours. Constipation is to be avoided. Discussing the medicinal treatment, the author says that it must aim to maintain an alkaline reaction in the urine and to render soluble and eliminate the uric acid accumulated in the organism. He suggests that acidity might be counteracted with sodium bicarbonate. The elimination of the uric acid is facilitated by an abundant diuresis. Since many patients with urinary lithiasis are subject to oliguria, the physician should prescribe a definite amount of fluid that is to be taken by the patient. To facilitate abundant diuresis he recommends that patients be given two large glasses of certain mineral waters half an hour before rising in the morning. Between meals the patient should also take mineral waters or a diuretic infusion. Further the author discusses the use of alkaline salts, of acid medication, of lithium salts, of salicylic acid, of methenamine, of piperazin, of cinchophen and finally of vitamin A.

**Gonadotropic Hormone in Serum of Normal Pregnancy and During Hyperemesis**—Legrand demonstrates that in the course of normal pregnancy the gonadotropic hormone is absorbed by the proteins of the maternal blood serum. However, in women with hyperemesis gravidarum there exists, in addition to this absorbed hormone, a large quantity of hormone which is not absorbed by the serum albumins but is free. The presence of this nonabsorbed hormone seems to be related to the development of the symptoms of hyperemesis gravidarum. The author reports the clinical histories of two women with hyperemesis gravidarum. The serum of these women contained large quantities of free gonadotropic hormone.

Results of Ten Years of Roentgen Therapy of Cancer of Cervix Uteri W. P. Plate—p. 280

**Hemorrhagic Pachysalpingitis**—Paucot and Bedrine do not maintain that hemorrhagic pachysalpingitis is more frequent than ectopic pregnancy, but they think that the systematic microscopic examination of hematosalpinx will disclose new cases of hemorrhagic pachysalpingitis. They report the history of a woman, aged 30, who presented symptoms which necessitated a laparotomy. After describing the observations in the course of the operation they give a detailed description of the macroscopic and microscopic aspects of the removed uterine tube. They stress the absence of the histologic characteristics of pregnancy, for there was no decidual transformation of the connective tissue and no signs of syncytium of Langhans. Discussing the existing microscopic changes they cite among others the fact that the hemorrhage is diffuse and involves the entire thickness of the tube and that the serosa is thickened and participates in the general hypertrophic reaction of the entire organ. Especial attention is given to the vascular changes, because they help to throw light on the pathogenesis. The authors say that they do not believe that the pathogenesis of hemorrhagic pachysalpingitis is uniform and that the infection with banal microorganisms is always responsible for its appearance. In the reported case there were several factors which spoke against such a pathogenesis and indicated that syphilis or hereditary syphilis played a part

The authors regard the condition more as a syndrome than as a definite disease and thus they differ with Bazy, who affirms that hemorrhagic pachysalpingitis has an absolute autonomy. They consider it as an anatomic reaction to various infections (bacterial or specific) of the uterine tubes. Finally they suggest that, as regards the etiology, hemorrhagic pachysalpingitis may perhaps be related to hemorrhagic pachymeningitis, for they were surprised by the similarity of the vascular lesions in these two processes.

\*Loss of Chloride and Vomiting L. Binet, D. Bargeton and J. Lacorne—p. 1681

\*Difficulty of Transformation of Carotene (Provitamin A) into Vitamin A in Course of Various Pathologic Conditions Therapeutic Consequences R. H. Monceaux—p. 1683

**Loss of Chloride and Vomiting**—Reports on hypochloremia and particularly on the part played by vomiting in its development, which were presented at the French medical congress (held in Marseilles in November), and observations on a woman with uncontrollable vomiting of pregnancy, induced Binet and his associates to study the role of vomiting in the loss of chlorides. They describe the clinical history of the woman and in diagrams they indicate the loss of chloride in the vomit, the changes in the chloride content of the blood and so on. The results of the chemical studies on the urine, the vomit and the blood induced the authors to employ in addition to other therapeutic measures also rechloridation in the form of daily intravenous injections of 20 cc of a 10 per cent solution of sodium chloride. After this treatment was instituted the vomiting gradually decreased. The authors recall an earlier report (1928) which likewise recommended the administration of sodium chloride in cases of uncontrollable vomiting of pregnancy. In the second part of this paper they describe their studies on the mechanism of the loss of chlorides by the process of vomiting. They made perfusion experiments on isolated lungs and stomachs and found that the blood perfusing the lung is not deprived of much of its chloride, however, the blood perfusing the stomach presents a constant and considerable impoverishment in chloride, which amounts to from 30 to 45 per cent. Regarding the therapeutic significance of these observations, they say that a severe loss in the chloride content of the organism should be counteracted by the administration of chloride. In acute cases, hypertonic solutions of sodium chloride should be given by intravenous injection. In this connection the authors direct attention to studies on dogs which revealed that, whereas the slow intravenous injection of 20 cc of a 10 per cent solution of sodium chloride was well tolerated, the rapid injection of 20 cc of a 30 per cent solution resulted in circulatory collapse.

**Transformation of Carotene into Vitamin A**—Monceaux points out that animal experiments have demonstrated that carotene administered in the form of a tested solution is capable of curing and preventing the disorders that are caused by a deficiency of vitamin A. However, the clinical problem is not as simple, for, whereas the healthy organism may be able to transform carotene into vitamin A, it is not so in numerous pathologic conditions. The author first directs attention to carotenemia, which is accompanied by yellow pigmentation of the skin simulating icterus. It occurs in tuberculous, cancerous, diabetic and obese patients and in children. It is due to the fact that the carotene is not properly oxidized. To counteract this carotenemia the physiologic activity and particularly the oxidative process must be augmented. Another disorder, which leads to defective utilization of carotene, with or without pigmentation, is hepatic insufficiency. It is possible that a hepatic insufficiency is a factor also in some of the aforementioned conditions of hypercarotenemia. Moreover it is probable that insufficient transformation of carotene into vitamin A will result in a deficiency of the A factor and may be followed by such disorders as hemeralopia, xerosis, pyodermitis and diarrhea. It has been proved also that the small quantities of carotene which are absorbed in the foods are entirely insufficient to supply the liver with the A factor, it is necessary to ingest massive doses. The author thinks that in view of the frequency of insufficient transformation of

carotene into vitamin A the treatment with the provitamin carotene should be abandoned and replaced by the administration of vitamin A in its direct and natural form as it is provided by certain types of fish. In this form it can be perfectly assimilated and kept in reserve. Moreover, it has been established that the growth factor of animal origin has an action that is twenty times more potent than pure carotene. Regarding the posology, the author says that studies by Busson disclosed that, if the organism's reserves are exhausted, the vitamin must be given in large doses daily for a long period. It is necessary to administer from 6,000 to 6,500 units of the natural vitamin A either in a single dose or in fractionated doses in the course of the day.

\*Epidural Sacral Route in Administration of Tetanus Antiserum C Tangari—p 268

**Tetanus Antiserum Epidurally**—Tangari points out the importance of the epidural sacral route for the introduction of tetanus antiserum in cases of grave tetanus. The injections are made at the hiatus sacralis with the patient in the prone position and by using a needle longer than ordinarily used in spinal puncture. The author used Behring's antiserum which was administered in daily doses of from 150,000 to 200,000 international units. Two daily injections of antiserum in doses of 20,000 international units each are administered to the patient, one of which is made in the subarachnoid space through the hiatus sacralis and the other in the epidural sacral space. The remaining dose of antiserum is administered to the patient in intravenous and intramuscular injections. A local treatment which consists in local disinfection of the wound, applications of alcohol pads, isolation of the patient from light and noise and the administration of purgatives and of light milk diet, is also given. The fifteen patients who recovered out of the group of sixteen who had the treatment did not suffer from paralysis or nervous complications. According to the author, the administration of antiserum through the sacral epidural route has the following advantages: 1. Lumbar puncture, which cannot be performed in cases of grave opisthotonos, can be replaced by puncture at the dorsal sac through the hiatus sacralis. Consequently the antiserum can be introduced in the subarachnoid space, even in grave opisthotonos. 2. The toxin diffuses itself down to the cauda equina and up to the nervous roots. Consequently the passage of the toxin to the subarachnoid space and to the nervous centers is blocked by anatomy. The duration of the contractures and the evolution of the disease are shortened. The treatment is not followed by complications. The technique is easy. The epidural sacral route has been resorted to, up till now, in the treatment of tetanus from wounds of the lower extremities, which are the most frequent and dangerous. It seems advisable to resort to it in the prevention of tetanus which is indicated in the presence of suggestive wounds of the lower extremities.

\*Bactericidal Power of Blood Serum Against Gonococcus in Normal Persons and in Gonorrhea in Course of Bacterial Vaccine Treatment G De Aldo—p 662  
Diagnostic Value of Most Common Cultural Methods for Identification of Diphtheria Bacillus V Lanza—p 673

### Bactericidal Power of Blood Against Gonococcus—

De Aldo made determinations, in vitro, of the bactericidal power of the blood of eleven normal persons and of nineteen patients suffering from gonorrhea. In the patients the determinations were made before and in the course of the administration of a bacterial vaccine which contains gonococci, streptococci, staphylococci and Bacillus coli. The author found that the bactericidal power of the blood against the gonococcus is more intense in persons who are ill than in normal persons.

It increases in acute urethritis in men as soon as seven days after development of the infection and still more as complications (prostatitis and epididymitis) develop. It is more intense in chronic than in acute forms of gonorrhea in women. It increases in the blood of patients of either sex after administration of bacterial vaccines by either the intravenous or the subcutaneous route and still more as the vaccinal treatment advances. According to the author the administration of bacterial vaccines increases the forces of defense of the individual against the gonococcus as well as the general and humoral immunity of the patients.

### Monosymptomatic Primary Cardiac Rheumatic Fever

—Bullrich and Snider say that rheumatic fever may develop with pain in the heart or in the precordial region as the only symptom of the disease, whereas articular symptoms may or may not be present. Monosymptomatic primary cardiac forms of rheumatic fever are frequent. In these forms the alterations of the electrocardiogram, especially those which show disturbances of the auriculoventricular conduction, may be the only sign of the disease aside from cardiac or precordial pain. The authors emphasize the importance of making electrocardiograms for an early diagnosis because of the fact that the disease rapidly regresses by early administration of large doses of sodium salicylate. The drug is prepared in an isotonic solution (232 Gm per thousand cubic centimeters) and administered in daily doses varying from 16 to 23 Gm, by enema and by the drip method. Discontinuation of the treatment is indicated by normalization of the electrocardiogram (or, in the presence of organic lesions which give electrocardiographic irreversible tracings, by disappearance of the auriculoventricular disturbances). As a rule pain subsides rapidly in the course of the treatment and fever disappears in from four to seven days. The electrocardiogram returns to normal (or shows disappearance of the auriculoventricular disturbances) in two or three weeks unless there are irreversible lesions. Even in this case further bouts are prevented by early administration of liberal doses of sodium salicylate. The treatment can be considered as a diagnostic and therapeutic test of rheumatic fever and also as a test of value for differentiating rheumatic fever from endomyocarditis caused by focal infection which does not subside by sodium salicylate treatment. The clinical and electrocardiographic study of six cases is reported. Four cases in the group were of the cardiac monosymptomatic form.

Symptomatic Convulsions and Focal Infection K Hansen—p 583

### Gastrogenic Psychoses—

Scheid reports the clinical histories of two patients in whom "obscure" forms of dementia developed. Both patients presented symptoms of funicular spinal disorders. Pernicious anemia could be excluded. Examination disclosed in both patients an achylia gastrica. An earlier examination of the first patient had revealed hematologic changes of a type which is characteristic for hypochromic anemia, but in the meantime these changes had been largely counteracted by suitable treatment. In the second patient a moderate secondary anemia still existed at the time of the psychiatric observation. In this patient the achylia was caused by a gastric scirrhus. In both patients the mental disturbances could be identified as "gastrogenic" psychoses. The author points out that by correspondingly directed internistic examinations it might be possible to detect more cases of this type among the psychoses of obscure etiology. He thinks that

particularly among the cases of unexplained dementia there are doubtless some "gastrogenic psychoses." Moreover, the psychoses of pernicious anemia, which are more readily recognized on account of their clear symptoms, can be classified with the gastrogenic psychoses.

Action of Close Range Roentgen Irradiation on Tumor Tissue W Shreier and H Huber—p 107

**Hydremia in Thrombosis and Embolism**—Schrifer says that changes in the vascular walls, in the form of varicose deformities in the network of the pelvic veins, play a part in the frequent thromboses after gynecologic prolapse operations. Although such varicose deformities are also frequent in pregnant and puerperal women, the incidence of thrombosis is much less during the puerperium and even after surgical deliveries than is the case after gynecologic operations. The author sees the cause of this physiologic protection against thrombosis on the one hand in the rapid venous backflow after the delivery of the child, and on the other hand in the hydremia which is already present before birth and which is increased immediately after. The author devotes the second part of his paper to the nature and action of hydremia and the third part to the clinical and hematologic estimation of hydremia in obstetrics and in surgical gynecology. Summarizing his observations, he says that hydremization is evidently of value in the prevention of postoperative thrombosis and embolism. This prophylactic action of hydremia is explained by a number of clinical observations. In adipose and cachectic patients in whom the water exchange is impaired, the danger of thrombosis and embolism is great, as is the case also in the presence of high temperatures and during the stage of premenstrual inspissation of the blood, however, in puerperal women and in patients who have been given large amounts of fluid the tendency to thrombosis and embolism is surprisingly low. In the course of the clinical and hematologic studies on hydremia the author investigated the action of an artificial postoperative dilution of the blood, induced by venesection and subsequent filling up with sodium chloride solution. With this method it was possible to reduce the incidence of thrombosis and embolism in cases of myoma and in benign tumors of the ovaries and of the adnexa. Further studies were concerned with determining the degree of hydremia by measuring the dry residues, the specific gravity in the total blood and in the serum, the viscosity of the blood serum and the hemoglobin and erythrocyte values. These investigations were made on seventy-nine parturient women and on 149 women undergoing gynecologic operations. Regarding the prognostic significance of the hydremia, the author says that in the women who underwent gynecologic operations and who were subject to embolism the hydremia values were near the lower limits of normality, but that these values did not permit the estimation of the dangers from thrombosis and embolism before the operation.

Operative Treatment of Cancer of the Stomach I Ya Slonim—p 363  
Hazards of Protein Therapy K V Stroykova—p 372

**Stomach After Resection for Ulcer**—Shekhter reports postoperative roentgenologic studies of sixty cases in which partial gastric resection was performed for ulcer. Observations on eleven patients were begun on the twentieth post-

operative day and were continued for three months. Ten of this group were studied for periods lasting two, three and five years. Observations on the remaining forty-nine patients were begun at a later period. The author concludes that resection brings about a marked alteration in the form and the tonus of the stomach depending on the type of resection and postoperative adhesions. Many patients with postoperative adhesions do not exhibit any complaints or objective signs. From a roentgenologic point of view, the first method of Billroth and its Haberer modification are to be considered preferable as far as motor function is concerned. Following these operations, food passes in the normal physiologic direction and there is established in most cases of the first Billroth operation and in all of the Billroth-Haberer operation a rhythmic evacuation of the stomach contents. The second method of Billroth leaves a smaller stomach and is characterized by filling of the afferent loop of the anastomosis and by accelerated emptying. The Finsterer modification of the second method of Billroth does not guarantee against the filling of the afferent loop. Shortly after the resection considerable inflammatory edema of the mucosa is observed, resulting in narrowing of the anastomotic stoma and retarded evacuation. This edema disappears in uncomplicated cases in the course of three months, leading to the restoration of the type and time of evacuation characteristic for the given type of resection.

**Chronic Appendicitis**—Plisan and Gringauz studied roentgenologically 142 cases of chronic appendicitis in which operative intervention was later resorted to. The patients were given barium sulfate orally from eight to ten hours before the commencement of roentgenologic observation, which was repeated several times in the course of the next two or three days. The appendix was visualized in ninety-five (67 per cent). Definitely localized tenderness was present in sixty-three (66.8 per cent). The authors consider x-ray study a valuable method in arriving at diagnosis of chronic appendicitis. Persistent irregular filling observed on repeated examination suggests a pathologic state. Failure to fill with the use of correct technic constitutes another important sign of chronic appendicitis. Strictly localized tenderness of the appendix combined with loss of its motor function and limitation of motion when combined with the foregoing signs is pathognomonic of chronic appendicitis.

Steatorrhea in Patient with Gastric Cancer S Lups and H Van Kooten—p 5307

**Cancers with Hollow Peduncle**—On the basis of case histories, Mansens describes a peculiar type of gastric and intestinal cancer. In one patient, a man aged 68, the rectal examination disclosed about 9 cm above the sphincter a tumor with a central crater and apparently a short peduncle. The tumor was movable against the basis. Since the patient refused a laparotomy, it was decided to remove the growth by way of the anus. The tumor, which was about the size of a cherry, was cut by diathermy. After the operation the patient had peritonitis and died. The necropsy revealed large quantities of fecal masses in the small pelvis and a defect of considerable size in the rectal wall. Examination of the removed tumor disclosed an adenocarcinoma that had grown deep into the muscularis. The portion extending beyond the muscularis had a papillary character. The entire thickness of the muscularis as well as the serosa was found in the removed portion, that is, the surgeon had unknowingly removed a portion of the intestinal wall. The author further cites two cases of gastric tumor in which the gastric wall was drawn up into the tumor so that the growth seemed to have a peduncle, which in these cases consisted of the tissues of the gastric wall. If the apparent peduncle of these tumors is sectioned

a large opening results, as was the case in the aforementioned fatal case of rectal carcinoma. In the stomach this is not so serious, because an extensive resection is usually made. The author regards the peculiar growth of papillary carcinomas as the factor that is responsible for this treacherous type of tumor.

Sedimentation Speed of Erythrocytes in Pulmonary Tuberculosis C. Lossati—p. 149

**Hyperchloremia and Hyperazotemia in Hemorrhage from Peptic Ulcer**—Borst says that several investigators observed an increase of urea in the blood of patients suffering from massive hemorrhage into the digestive tract but that, as regards the cause of this hyperazotemia, the opinions are divided. At the author's clinic it was observed that the majority of the patients with hemorrhage into the digestive tract who had marked azotemia showed hyperchloremia but at the same time an extremely low excretion of sodium chloride in the urine. In order to obtain a better insight into the cause of this azotemia and hyperchloremia a special study was made of all patients suffering from recurrent massive gastric hemorrhages. The three most extensively studied cases are reported. Summarizing his observations, the author says that the hyperazotemia that appears with massive bleeding into the digestive tract is due to an increased formation of urea from the blood within the intestine. Should the patient be insufficiently fed, catabolism of body protein takes place, during the bleeding, however, it is slight, since the blood within the intestine serves as nourishment. Toxic destruction of body protein did not occur in the reported cases. The hyperazotemia leads to relative polyuria, as a rule the urine output surpasses the fluid intake. The urea concentration of the urine remains maximal until the posthemorrhagic blood dilution has restored the volume of the circulating blood. If the patient, by repeated massive bleeding or by operation, develops shock, both the diuresis and the maximum urea concentration of the urine drop and the urea content of the blood rises still more. The drop in the urea clearance is more marked than that of the blood pressure. The clearance is possibly the best measure for the severity of the shock. The posthemorrhagic blood dilution is retarded by high diuresis with a restricted fluid intake, by low albumin content of the blood, and especially by damage to the capillaries caused by operative shock. As long as the posthemorrhagic blood dilution is still in progress, the kidneys excrete practically neither sodium nor chlorides, if sodium chloride is administered, the sodium chloride content of the blood plasma rises far above the normal. In this period the urine carries much potassium, whereas the potassium content of the blood is normal or reduced. The retention of sodium chloride and the increased excretion of potassium form, in all probability, part of a regulating mechanism established for the purpose of restoring the normal filling of the arterial system by way of an augmentation of the total extracellular fluid and therefore of the blood plasma. Possibly this same mechanism is encountered in all situations in which the arterial system is incompletely filled. Regarding the treatment the author says that, following massive hemorrhage, the body must be aided in its effort to restore the amount of circulating blood (1) by restoring as far as possible the loss of erythrocytes and plasma protein, for this purpose the drip transfusion can be strongly recommended, and (2) by administering fluid until the urea concentration of the urine drops below the maximum and the chloride content rises, the presence of edema

is no contraindication for a liberal administration of fluid. Salt may be given only when the sodium chloride content of the blood plasma is not elevated. Carbohydrates should be administered as soon as possible so as to prevent body protein destruction by marfanism. In the presence of vomiting or other signs of gastric retention, the author gives a 5 per cent solution of dextrose subcutaneously, otherwise 10 per cent case sugar with a few drops of orange juice by mouth. This latter is well tolerated by most patients.

**Tuberculous Epididymitis**—Ljunggren states that tuberculous epididymitis usually has a chronic course but is acute in about 17 per cent of the cases. Differential diagnosis between the chronic cases and the so called chronic epididymitis may be difficult. Palpation by the rectum often gives decisive results for the diagnosis of tuberculous epididymitis, since tuberculous changes in the prostate and seminal vesicles can be established in about two thirds of the cases. Such changes in the prostate can sometimes be demonstrated by urethrography. X-ray examination of the epididymis does not as a rule give valuable information for diagnosis. As renal tuberculosis occurs simultaneously with tuberculous epididymitis in about one fourth of the cases, intravenous pyelography is advised. If epididymectomy can be carried out, it is the method of choice in tuberculous epididymitis, and it is advised in every more pronounced chronic epididymitis suspected to be tuberculous, for long expectant treatment, the author says, entails the risk that the testis may become infected if the process is tuberculous. He emphasizes the importance of long continued careful dietetic hygienic treatment after the operation, to promote the resistance of the organism to the tuberculous infection in the body, and of constant control for at least three years.

**Serum Treatment of Pneumococcal Pneumonia**—Brastrup and his co-workers discuss the result of type specific serum treatment in seventy six cases of lobar pneumonia (in forty children, thirty-six adults), representing practically all the pneumonias in Skive and its vicinity from January to August 1938, 70 per cent were type I, 17 per cent type VII. The total mortality was 39 per cent, the mortality in the uncomplicated cases 14 per cent. The authors say that attainment of the best results depends on understanding and support on the part of the practicing physician with consequent earliest possible hospitalization, earliest possible type determination in the hospital laboratory and the administration of large doses. They advise from 40,000 to 60,000 units for children under 13, from 160,000 to 220,000 for adults, and as far as possible one large single dose, individualization is necessary. The inconveniences and dangers of serum sickness, they find, are not grave enough to hinder the application of serum treatment in any case of lobar pneumonia. Transportation to the hospital in the first days of illness is without harmful effects of consequence.

## LEUKEMOID REACTIONS OF THE MYELOID TYPE

FRANK J HECK, M D  
AND  
BYRON E HALL, M D  
ROCHESTER, MINN

By the term leukemoid reaction is meant a blood picture that closely resembles or is indistinguishable from, that of the various types of leukemia. At necropsy, however, leukemic changes in the organs and tissues of the body are lacking. Reactions of the leukemoid type have been recognized for many years, and it is now known that they occur with a wide variety of pathologic conditions. Our experience leads us to believe that they are much more frequently encountered than was formerly thought. Since it is essential that these reactions be distinguished from the leukemias, it is important that practitioners in all branches of medicine have a general idea concerning those diseases with which leukemoid reactions may be encountered.

In attempting to group these leukemoid reactions, we realize that some of them might well be placed under two headings. As time goes on, however, other groups of cases will undoubtedly be described in which this type of reaction occurs so that the classification is not complete.

### INFECTIONS

*Pyogenic Type*—The majority if not all of the bacterial infections are associated with quantitative and qualitative alterations in the blood picture. The type of cellular reaction that develops varies with the type of organism causing the infection. Since the scope of this paper is restricted to leukemoid reactions of the myeloid type, no attempt will be made to discuss the lymphatic reactions of pertussis, typhoid fever, infectious mononucleosis and certain other diseases.

Most acute and many chronic infectious diseases, especially those due to the pyogenic bacteria, are accompanied by neutrophilic leukocytosis. The eosinophils and basophils are reduced in number or are entirely absent, and the number of lymphocytes is diminished. The lymphocytopenia usually is relative rather than absolute. The qualitative blood picture is characterized by a "left shift" in the nuclei of the neutrophils, alterations in the cytoplasm, "toxic" granulation, increased basophilia and in some cases vacuolation. The degree of left shift in the nuclear pattern appears to be dependent on the virulence of the infecting organisms, the resistance of the host, the extent of the infection and

the reactivity of the bone marrow. As a general rule, the more severe the infection the greater the number of immature forms observed in the circulation. In cases of an overwhelming infection the bone marrow may ultimately fail to respond to the demand placed on it and leukopenia may be observed. A left shift in the neutrophils, however, is almost invariably demonstrable in the blood in these cases. The finding of myelocytes and promyelocytes in the circulating blood of patients with a severe infection is rather common, more rarely leukoblasts and even myeloblasts may be observed. This is not as infrequent an occurrence as was formerly believed. Leukemoid reactions with immaturity of the leukocytes going back to the stem cells have been reported<sup>1</sup> or have been observed by us in cases of pneumonia, pyelonephritis, peritonitis, empyema, pulmonary abscess, osteomyelitis, septicemia, puerperal sepsis and mastoiditis. Downey, Major and Noble<sup>2</sup> reported a case of appendical abscess with suppurative phlebitis of the portal system and the subsequent formation of abscesses in the liver, in which a pronounced leukemoid reaction was observed.

The following case exemplifies the development of a leukemoid reaction during the course of a severe infection.

CASE 1—A white man aged 55 came to the Mayo Clinic in 1927 because of extensive osteomyelitis involving the lower half of the right tibia and of the right fibula. He was emaciated and had a marked pallor. The value for hemoglobin was 38 per cent (Dare) on admission, the erythrocytes numbered 2,220,000 and the leukocytes 30,600 per cubic millimeter of blood. Eight days later a septic type of fever developed, the temperature ranging from 97 to 103 and 105 F daily. An enlarged spleen was noted.

The left kidney was explored, and a perinephritic abscess was found and drained. The patient continued to have a septic type of temperature curve postoperatively, and finally, shortly before his death, the leukocyte count rose to 133,000. The value for hemoglobin was 45 per cent. The erythrocytes numbered 2,520,000 per cubic millimeter, and the differential count revealed the following percentages: lymphocytes 0.4, neutrophils 90.2, monocytes 1.8, neutrophilic metamyelocytes 2.4, neutrophilic myelocytes 3.4, neutrophilic promyelocytes 1.6 and leukoblasts 0.2. Examination of blood smears showed a severe toxic-infectious blood picture with myeloid immaturity to the stem cells. At necropsy multiple abscesses were found in the spleen, prostate gland and both kidneys.

Leukemoid reactions are comparatively common with acute infections or acute exacerbations of chronic infections, occurring more frequently in children than in adults. As a general rule they can be distinguished

From the Division of Medicine, the Mayo Clinic.  
Read before the Section on Pathology and Physiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

from myelogenous leukemia with little difficulty on the basis of both the clinical picture and the hematologic data. The site of the infection is in most cases evident. The presence of a toxic-infectious blood picture is of considerable aid in diagnosis. It is not pathognomonic, however, for one may occasionally encounter it in cases of myelogenous leukemia with or without a secondary infection.

**Nonpyogenic Type**—With subacute bacterial endocarditis one may find myeloid immaturity in the circulating blood, and toxic changes or a left shift in the neutrophils may be lacking.

**Tuberculosis**—There are a number of reports in the literature of cases of tuberculosis in which, prior to postmortem examination, the diagnosis was either acute or chronic myelogenous leukemia. At the time of necropsy, however, there was no evidence of leukemia and the "leukemic" blood picture was explained on the basis of the tuberculosis.<sup>3</sup> In these cases myeloid tuberculosis was not found in the bone marrow, so that it would seem probable that the leukemoid reaction was due to toxemia. In those cases in which myeloid involvement of the bone marrow occurs, it would seem likely that the appearance of young forms in the circulating blood might be due to irritation of the cells of the marrow.

#### BLOOD DYSCRASIAS OR RETICULO-ENDORITIAL DYSRASIA

**Hemolytic Anemias**—The hemolytic anemias are accompanied by signs in the peripheral blood of increased regenerative activity of the bone marrow. If the process of hemolysis is acute the leukocytes and blood platelets in the circulation are increased and examination of stained blood films discloses large numbers of reticulated erythrocytes, polychromatophilia, anisocytosis, nucleated erythrocytes and more rarely, younger forms of the erythrocytic series. Immature cells of the myeloid series not infrequently are observed and in some cases are comparatively numerous. Leukemoid reactions of the myeloid type have been observed during the "crises" of congenital hemolytic icterus and sickle cell anemia, in association with the acute hemolytic anemia of Lederer, paroxysmal hemoglobinuria and the hemolytic anemias due to poisoning by chemical substances, and in rare cases of hemolytic anemia of indeterminate origin.

The following is a case in point.

**CASE 2**—A white woman aged 28 was admitted because of marked weakness, pallor and nervousness. There was no history of jaundice, and the pallor had been noticed for only a fortnight. The thyroid gland was palpable. The edge of the liver extended 4 cm below the costal margin. Splenic dullness was increased, although the edge of the spleen could not be palpated. On admission the value for hemoglobin was 41 Gm per hundred cubic centimeters and the erythrocyte count was 930,000 per cubic millimeter of blood. Morphologic examination showed extremely active regeneration, the reticulated erythrocytes being 85 per cent of the total number of cells. The remaining erythrocytes were deeply stained, spherical microcytes. Many normoblasts were present. The corrected leukocyte count was 16,800 per cubic millimeter. A differential count revealed the following percentages: neutrophils 60.6, lymphocytes 22.6, monocytes 7.6, eosinophils 0.3, metamyelocytes 4, myelocytes 1.3, promyelocytes 2 and leukoblasts 1.6. A fragility test showed hemolysis beginning in a 0.5 per cent sodium chloride solution and complete in a 0.36 per cent solution. The concentration of serum bilirubin was 13 mg per hundred cubic centimeters. Subse-

quently the edge of the spleen became palpable. On the basis of the enlarged spleen, the blood picture and three fragility tests showing increased hemolysis of erythrocytes, a diagnosis of hemolytic jaundice was made. Further observation raised the question of exophthalmic goiter, two basal metabolism determinations giving values of plus 27 per cent and plus 25 per cent.

Splenectomy was performed with the erythrocyte count at 1,010,000. The spleen weighed 882 Gm. Two months later the value for hemoglobin was 121 Gm and the erythrocyte count was 3,230,000 and the leukocyte count 8,800. Morphologically there was marked microcytosis and increased regeneration, the percentage of reticulated erythrocytes being 10. Nine months later thyroidectomy was performed for exophthalmic goiter, the basal metabolic rate being plus 49 per cent. Convalescence was uneventful and the patient has remained in good health.

In most cases of congenital hemolytic jaundice the diagnosis may be made readily on the basis of a history of recurrent attacks of jaundice, a relevant family history, splenomegaly, the characteristic blood picture and increased fragility of the erythrocytes to hypotonic saline solution. This case is of unusual interest, however, because the myeloid immaturity associated with an elevated leukocyte count, splenomegaly and an increased basal metabolic rate might well have led one to make an erroneous diagnosis of chronic myelogenous leukemia. In addition, except for a small number of microcytes, there was generalized macrocytosis due to the markedly increased regeneration of the erythrocytes. There was no history of jaundice and the value for serum bilirubin was not elevated at the time of admission. The family history was not pertinent. The diagnosis of hemolytic jaundice was made on the basis of the characteristic microcytosis associated with increased regeneration of the erythrocytes and the occurrence of a period of increased destruction of blood while the patient was under observation. The finding of increased fragility of the erythrocytes to hypotonic saline solution was helpful, although this phenomenon may be observed in rare cases of leukemia.

**Pernicious Anemia**—With this condition one may see leukemoid reactions at two different times.<sup>4</sup> They occur first when the patient is in relapse and particularly when the erythrocyte count falls below 2,000,000 per cubic millimeter of blood. The degree of immaturity varies, myelocytes and promyelocytes being present when the erythrocyte count is above this level. With an erythrocyte count of 2,000,000 or less, immaturity to the myeloblast may not infrequently be found. At times this immaturity is so marked that the question of leukopenic myelogenous leukemia arises. As a rule the microcytosis and the persistence of increased lobulation in the neutrophils enable one to distinguish the condition from myelogenous leukemia. Occasionally, however, these signs, particularly the macrocytosis, are absent, so that one must depend on the clinical history as an indication for the institution of treatment with potent material. There are also instances of myelogenous leukemia in which there is rather marked macrocytosis, but in these the leukocytosis and the immaturity are usually much more marked than one would expect in association with pernicious anemia and the increased lobulation in the neutrophil is absent.

In either spontaneous or induced remissions of pernicious anemia the leukocyte count increases at the time the reticulated erythrocyte response occurs. A value of 27,500 leukocytes per cubic millimeter of blood during a spontaneous remission has been reported, and one of our patients had a leukocyte count of 22,500.

4 Heck F. J. Myeloid Immaturity in Pernicious Anemia. *Am J Clin Path.* 2: 443-448 (Nov.) 1932.

during an induced remission. If the blood smear is first seen at this time, the number of immature cells will be found to be increased, and if leukocytosis is present the question of myelogenous leukemia is raised. If in addition there is splenomegaly, as there may be in from 40 to 50 per cent of cases of severe pernicious anemia, the difficulty in diagnosis is increased. The problem can be settled by the injection of adequate quantities of potent material and by observation for a period of two weeks. If the pernicious anemia is adequately treated, all the immaturity will disappear by the end of this time, whereas this does not happen in association with chronic myelogenous leukemia. It is important that relatively large amounts of potent material be given, for in several instances there has been no response in the blood when amounts of liver extract were injected that would ordinarily bring about an optimal response of reticulated erythrocytes.

The following is an illustrative case.

**CASE 3**—A man aged 54, admitted Jan 3, 1930, complained of weakness and loss of sensation in his feet. A diagnosis of pernicious anemia had been made eleven months previously, and he had improved satisfactorily under liver therapy. A relapse had followed discontinuance of the liver therapy. On admission the value for hemoglobin was 20 per cent and the erythrocytes numbered 1,010,000 and the leukocytes 1,800 per cubic millimeter. The patient was given a diet containing half a pound (0.2 Kg) of raw swine stomach a day, but after a day this was changed to Lilly's liver extract 343, eight vials a day being given after the first day. On January 6 before treatment was begun, the leukocyte count was 3,100 per cubic millimeter and the differential count showed the following percentages: neutrophils 75.8, lymphocytes 20.8, monocytes 1.8, eosinophils 1.2, promyelocytes 0.2 and leukoblasts 0.2. On January 14, eight days later, the leukocytes numbered 22,600 and the differential count showed the following percentages: neutrophils 37.2, lymphocytes 9, monocytes 5.2, eosinophils 5.2, basophils 0.4, metamyelocytes 14.2, myelocytes 11.6, promyelocytes 13, leukoblasts 3.6 and myeloblasts 0.6. By January 15 fifteen days after the beginning of treatment, the differential count was normal.

This case demonstrates the leukemoid reaction associated with untreated pernicious anemia as well as the reaction occurring during the height of the response to treatment and coincident with the response in the reticulated erythrocytes.

**Polycythemia Vera**—Leukemoid reactions are not uncommon with polycythemia vera. Elevated leukocyte counts are observed almost invariably in patients with this disease, the counts usually ranging from 10,000 to 30,000 cells per cubic millimeter of blood. Counts above 30,000 occur not infrequently, and counts in excess of 100,000 have been reported. More rarely, normal or low leukocyte counts are observed. Although immature myeloid elements are seen in the peripheral blood of only a relatively small proportion of patients, they occur far more frequently than was formerly believed. Most of the patients die as a result of some complication of the disease, but isolated reports have appeared of cases of long-standing polycythemia in which anemia gradually developed and the full-blown picture of myelogenous leukemia was present.<sup>5</sup> The

following case is of interest because of the opportunity to observe the patient over a prolonged period.

**CASE 4**—A white man aged 56, who came to the clinic first in 1917, was found at that time to have an enlarged spleen extending 2 cm below the costal margin. The value for hemoglobin was 100 per cent (Dare), the erythrocytes numbered 7,640,000 and the leukocytes 9,000 per cubic millimeter of blood. A differential count revealed 90 per cent neutrophils, 7 per cent lymphocytes, 0.3 per cent eosinophils and 2.7 per cent basophils. A diagnosis of polycythemia vera was made.

The patient returned to the clinic in 1928, eleven years later, because of weakness and epigastric discomfort after meals. Examination disclosed an enormously enlarged spleen extending to the pubis. The value for hemoglobin was 60 per cent (Dare), the erythrocyte count was 4,640,000 and the leukocyte count 110,000 per cubic millimeter. A differential count revealed the following percentages: lymphocytes 5, neutrophils 82, eosinophils 2, basophils 4, metamyelocytes 0.5, myelocytes 1, promyelocytes 4 and leukoblasts 1.5. The blood viscosity was 1.57. The total plasma volume was 4,145 cc, or 67 cc per kilogram, and the whole blood volume was 8,300 cc, or 133 cc per kilogram. The basal metabolic rate was plus 38 per cent. After a course of radium and roentgen therapy the patient was much improved, the spleen having been greatly reduced in size.

The patient was seen on several occasions in the course of the next two years, the values for hemoglobin and for erythrocytes and leukocytes remaining elevated and the spleen enlarged and myeloid immaturity continuing to be present in the blood smears. The patient died in 1930. Necropsy was not performed.

It is beyond the scope of this paper to enter into a discussion as to whether one is justified in terming the diagnosis in such cases polycythemia vera with a leukemoid reaction or genuine chronic myelogenous leukemia. In the majority of cases of polycythemia vera there are no immature myeloid cells in the peripheral blood stream. Furey<sup>6</sup> found that from 9 to 10 per cent of a series of 120 patients with polycythemia vera had young myeloid elements in the circulating blood either at the time they were first seen or subsequently during the polycythemic phase before treatment was instituted.

As has been said, it is a well established fact that certain patients with polycythemia vera have anemia eventually and chronic myelogenous leukemia finally. At necropsy there is myeloid metaplasia in the spleen, liver and various other organs. Other patients with polycythemia vera, like patient 4, have splenomegaly, an elevated leukocyte count and myeloid immaturity in the circulating blood but not anemia. Zimmermann<sup>7</sup> observed a case of this kind in which death occurred at a time when the erythrocytes numbered 6,230,000 and the leukocytes 63,650 per cubic millimeter and young myeloid elements were present in the peripheral blood. At necropsy myeloid metaplasia was found in the spleen and liver. A few cases have been reported in which the condition began with the picture of chronic myelogenous leukemia and terminated with that of polycythemia.<sup>8</sup> Thus there is considerable evidence in support of the view that polycythemia vera is a disease of the bone marrow analogous to myelogenous leukemia and that both diseases are the result of neoplastic involvement of the erythrogenic and leukogenic cells in the marrow. However, in view of the fact that such a relationship has not been conclusively proved, and because the majority of patients with polycythemia vera do not exhibit immature myeloid elements in the blood

## HARBORVIEW DIVISION

ture of the disease in roentgenograms of the skull, pelvis, ribs and long bones. The leukocyte count was 3,900 per cubic millimeter, and the differential count revealed the following percentages: lymphocytes 35.6, monocytes 7.3, neutrophils 45.6, basophils 0.6, metamyelocytes 4, myelocytes 0.3, promyelocytes 5, leukoblasts 0.3 and myeloblasts 1.3.

The diagnosis of multiple myeloma in this case appears to have been justified on the basis of the roentgenographic evidence and the Bence Jones proteinuria. Since necropsy was not performed, the possibility of metastatic carcinoma in the bone marrow arising from an undetermined primary site cannot be excluded with certainty.

**Osteosclerosis**—Osteosclerosis and Albers-Schonberg disease may produce a marked leukemoid reaction. One of Mettler and Rusk's<sup>12</sup> patients with osteosclerosis had been treated for three years for chronic myelogenous leukemia, there were anemia, splenomegaly and a typical picture of chronic myelogenous leukemia morphologically. As a rule the degree of immaturity is not marked, but in this case the smears showed 64 per cent myeloblasts before termination of the disease. In some instances roentgenographic examination of the bones discloses thickening of the cortex or the changes associated with Albers-Schonberg disease. Biopsy of the bone marrow shows an increase in fibrosis in the marrow. Aspiration of the marrow and examination of the material would probably fail to show the presence of such a fibrotic change.

## MISCELLANEOUS CONDITIONS

**Diabetic Coma**—This is commonly associated with leukocytosis and a leukemoid reaction. The myeloid immaturity disappears promptly after the institution of measures for control of the diabetes. The following case is illustrative.

**CASE 11**—A man aged 52 was admitted to the hospital in profound diabetic coma. The initial value for blood sugar was 882 mg, and the carbon dioxide-combining power was 7.8 cc per hundred cubic centimeters of blood. The leukocyte count was 25,000 per cubic millimeter. A differential count showed 84.4 per cent neutrophils, 9.7 per cent lymphocytes, 0.3 per cent basophils, 2.3 per cent monocytes, 2.3 per cent metamyelocytes, 0.7 per cent myelocytes and 0.3 per cent promyelocytes.

The patient died within twenty-four hours after admission. Necropsy showed no lesion which would account for the leukemoid reaction.

**Chemical Poisoning**—Leukemoid reactions of the myeloid type occur rarely in cases of chemical poisoning. Downey, Major and Noble<sup>2</sup> observed leukemoid reactions in three patients, all in the same family, each of whom had dermatitis associated with a relatively severe systemic reaction following the application for scabies of an ointment, supposed to contain mercury, over the skin of the entire body. Leukocytosis associated with a left shift to the stem cells was observed in the blood in each case.

Leukemoid reactions likewise have been observed in cases of mustard gas poisoning<sup>1a</sup> and in occasional persons who have been poisoned by phenylhydrazine, as in the following case.

**CASE 12**—A man aged 52 whose condition had been diagnosed as polycythemia vera on the basis of episodes simulating petit mal and elevated values for hemoglobin and erythrocytes was given 0.2 Gm of phenylhydrazine hydrochloride orally

each week. Studies of blood volume had not been performed. At his examination at the clinic six months later the value for hemoglobin was 121 Gm and the erythrocytes numbered 4,080,000 and the leukocytes 7,200 per cubic millimeter. The differential count showed 26 per cent lymphocytes, 65 per cent monocytes, 63 per cent neutrophils, 1 per cent eosinophils, 0.5 per cent basophils, 0.5 per cent metamyelocytes, 1 per cent myelocytes and 1.5 per cent promyelocytes. Erythrocytic regeneration was increased. The blood viscosity, hematocrit values and blood volume were normal. Phenylhydrazine therapy was discontinued, and the patient was examined three months later. The blood volume was normal and examination of the blood gave negative results at that time, the myeloid immaturity having disappeared from the circulating blood during the interim. It was felt therefore that the myeloid immaturity was the result of the phenylhydrazine therapy and that polycythemia vera was not present. A final diagnosis of petit mal was made.

**Indeterminate Leukemoid Reactions**—Not all leukemoid reactions can be satisfactorily classified. In our material we noted that in 1934 one patient had a leukocyte count of 45,000 per cubic millimeter with the morphologic picture ordinarily associated with chronic myelogenous leukemia. She was known to have had myeloid immaturity in 1933. Resection of the stomach had been carried out for a gastric ulcer, but when the patient was seen in 1934 there was nothing to suggest a lesion that would account for a leukemoid reaction. A diagnosis of chronic myelogenous leukemia was made and the patient was given roentgen therapy. In 1938 the blood was normal in every respect. The patient died after exploration for an obstructing lesion of the colon. At necropsy there was no evidence of myelogenous leukemia. The normal blood picture and the lack of evidence of leukemia at necropsy make it necessary to classify the condition in a case of this kind as an indeterminate type of leukemoid reaction.

## COMMENT

The importance of differentiating leukemoid reactions from the leukemias is obvious. In most cases this differentiation can be made on the basis of the clinical observations. The hematologic picture may or may not be of additional aid in diagnosis. The total leukocyte count is of relatively little or no diagnostic significance unless it is in excess of 100,000 cells per cubic millimeter of blood. Leukocyte counts above this are observed rarely with conditions other than the chronic forms of leukemia. It should be remembered that many patients with leukemia, including the chronic variety, have total leukocyte counts which fall either within or below the range for normal persons. In a study previously made by one of us, approximately 40 per cent of all patients with acute leukemia and 10 per cent of all patients with chronic leukemia seen at the Mayo Clinic from 1928 to 1933 inclusive had leukocyte counts below 10,000 cells per cubic millimeter.<sup>13</sup>

## SUMMARY

Leukemoid reactions occur commonly with infections, with blood dyscrasias and diseases of the reticulo-endothelial system, with diseases in which there is invasion and irritation of the bone marrow (as in metastasis to bone), with conditions in which there is an increased demand on the bone marrow (such as severe and sudden loss of blood) and with chemical poisoning. Occasionally cases are encountered in which no satisfactory explanation for the leukemoid reaction can be made.

<sup>12</sup> Mettler S. R. and Rusk G. Y. Fibrosis of the Bone Marrow (Myelofibrosis) Associated with Aleukemoid Blood Picture. Report of Two Cases. *Am J Path* 13: 377-388, 1937.

<sup>13</sup> Heck F. J. Unpublished data.

As a rule, because of associated morphologic or clinical observations, differentiation of the leukemoid reaction from chronic myelogenous leukemia on a clinical basis is simple. There are instances, however, in which the differentiation cannot be made satisfactorily on the basis of present knowledge. We should again like to stress the necessity for the correlation of the history, physical appearances and laboratory data in making the diagnosis in cases in which leukemoid reactions are present.

#### ABSTRACT OF DISCUSSION

DR HARRY A WICKOFF, San Francisco. This subject is always with us in the sense that throughout the work of the day the more closely one studies the reports of ordinary blood examinations as they come from the laboratory the more often one sees leukemoid or what one considers leukemoid reactions, especially in association with the infections. Of course, as the authors pointed out, one can well obtain the clinical data in such cases, so that the pictures seen ordinarily in routine work are easy to evaluate, if not on morphologic aspects at least with the help of the available clinical data. I had the advantage of having looked over the authors' paper in advance of the reading and had time to think of one or two of the things I had seen myself that rather parallel the cases mentioned. As Dr Krumbhaar pointed out in 1926, conditions associated with leukemoid reactions are of two general kinds: those that are really difficult to differentiate from leukemia and those that have only hematologic similarity. It is with the first group that both the clinical pathologist and the clinician are mostly concerned, and naturally Drs Heck and Hall considered some cases of such conditions in their paper. Their discussion of these cases is helpful. Conditions of the second type (those that have only a hematologic similarity) are an important and constant matter of consideration in any laboratory where large numbers of blood examinations are made. Usually they present little difficulty in evaluation especially when clinical data are available. I recall a case of polycythemia in which the following levels were reached: red cells 7,500,000 per cubic millimeter, hemoglobin 175 Gm per hundred cubic centimeters and white cells 19,250 per cubic millimeter, with 85 per cent neutrophils, moderate myelocytosis and moderate normoblastosis. Massive splenomegaly developed. Four years afterward the red cell count was 4,100,000, the hemoglobin content was 112 Gm and the white cell content was 17,100, with 72 per cent neutrophils and 7 per cent myelocytes. The spleen was still very large. After five years the red cell count had fallen to 3,000,000, the hemoglobin content to 10 Gm and the white cell count to 15,100, with 4 per cent basophils and 16 per cent myelocytes. The level for platelets, which had formerly been well elevated but within normal limits had fallen below 200,000 per cubic millimeter. Cells in the blood stream more primitive than myelocytes were not noted, and the bone marrow obtained from the sternum at about this time showed an extensive erythroblastic proliferation with somewhat less intensive granulopoietic hyperplasia at the myelocytic level.

DR NATHAN ROSENTHAL, New York. Drs Heck and Hall have reported an unusually interesting group of cases. It is remarkable that such leukemoid reactions occur with so many different diseases, cognizance of which will prove to be of some importance in diagnosis. I have had similar experience, such that the diagnosis was difficult when I saw the patient for the first time. It seems that leukemoid reactions occur with three main conditions: first, with unusual forms of infection, especially in cases of pyonephrosis in which the mass may be mistaken for the spleen if it is on the left side, second, with acute hemolytic anemia, especially of the Lederer type, and, third, with polycythemia. With polycythemia the leukemic blood picture may be present at the same time as the erythremia, or it may develop when the polycythemia becomes spent, which is usually in a terminal phase of this disease. The cases of osteosclerosis in which the bone marrow becomes fibrotic offer some difficulty in diagnosis unless sternal biopsy is made during life. In such cases there are usually a sec-

ondary enlargement of the spleen and development of a leukemic blood picture. Some authorities even consider the disease leukemia with secondary or terminal myelofibrosis. Recently I have had exceptionally good results in differentiating leukemoid blood pictures from true leukemia by studying the bone marrow obtained by sternal puncture. It is possible that this may be a helpful procedure for the establishment of an early diagnosis.

DR FRANK J HECK, Rochester, Minn. We did not have time to present all the statistical data we should like to have given, but in a practice such as ours, where we see the patient once, make a diagnosis and see him no more in as high as 30 or 40 per cent of instances, the patient may show a leukemoid reaction when he has metastatic bone involvement. I should like to emphasize the point Dr Rosenthal has made. Cases of osteosclerosis are extremely rare, but sternal biopsy is of course necessary in them, since sternal puncture will fail.

#### THE COURSE AND TREATMENT OF THROMBOPENIC PURPURA

NATHAN ROSENTHAL, M.D.

NEW YORK

Thrombopenic purpura is characterized by uniformity in its blood picture but presents marked variations in its severity and clinical course from acute to chronic.

The study on which the present article is based comprised 153 cases observed over ten years (1926 to 1936). The following typical blood conditions were noted in this group: (1) absence of anemia, unless considerable bleeding had taken place, (2) absence of abnormalities in the leukocytic picture and (3) marked diminution in the number of platelets. In addition, the bleeding time was prolonged, clot retraction was absent and a positive capillary resistance reaction present.

Symptoms of bleeding were present in all cases, these included easy bruising, spontaneous ecchymosis, purpura, epistaxis and bleeding gums. There was considerable variation, however, in the amount of bleeding, which frequently was severe at first but usually was mild in cases of more chronic disease. Bleeding was especially severe when associated with menorrhagia and occasionally with cerebral hemorrhage.

During the period of observation of such a large group of cases there was an opportunity to evaluate the various kinds of treatment advocated for this disease. Included among our 153 cases are fifty cases in which treatment was with snake venom, reports of which have previously been published.<sup>1</sup> Recent cases under observation have not been included in the present report, as sufficient time has not elapsed for a proper follow-up. Symptomatic purpura as the result of leukemia, subacute endocarditis and various forms of splenomegaly have not been considered in this communication.

#### CLASSIFICATION OF CASES

*According to Age*—The incidence of the condition in this series during the first decade of life was remarkable, 29 per cent. This is in approximate agreement

From the Medical, Surgical and Pediatric Departments the Mount Sinai Hospital.

Read before the Section on Pharmacology and Therapeutics at The Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

1. Peck S. M. and Rosenthal Nathan. Effect of Moccasin Snake Venom (*Anistrodon piscivorus*) in Hemorrhagic Conditions. *J. A. M. A.* 104: 1066 (March 30) 1935. Peck S. M., Rosenthal Nathan and Erl L. A. The Value of the Prognostic Venom Reaction in Thrombocytopenic Purpura. *ibid.* 106: 1783 (May 23) 1936. Purpura. with observations in the collected cases of Wintrobe, Hanrahan and Thomas,<sup>2</sup> who reported 36.2 per cent for the same age period. During the next three decades the average incidence was about 17 per cent, it occurs less frequently after the fortieth year. The acute form is encountered more often during infancy and childhood, whereas the chronic form occurs more frequently during adult life. Between the ages of 1 and 20 years, and especially during the first decade of life spontaneous recovery occurred in an unusually large number of instances (thirty-three cases compared with nine in adult life, excluding cases of drug idiosyncrasy). There have been no recurrences in these cases, which have been under observation from three to ten years. The absence of recurrences is of especial importance and should be kept in mind in gauging the effect of any form of treatment in children. The period of recovery varied from two weeks to seven months, and in one case (in which there was associated rheumatic fever) to as long as two years.

Classification of Cases

	Birth to 20 Years	21 Years and Over	Total
I Spontaneous recovery			
A Acute idiopathic	22	8	30
B Acute with infection	4	1	5
C Acute postinfectious	7	0	7
D Drug idiosyncrasy	1	10	16
II Acute			
A Fatal (without operation)	4	2	6
B Splenectomy			
1 Well	1	3	4
2 Died	2	1	3
III Neoplastic involvement	0	7	7
IV Chronic			
A Under observation	13	23	36
B Fatal (without operation)	0	3	3
C Splenectomy			
1 Well	12	13	25
2 Improved	2	1	3
3 Died			
(a) Postoperatively	1	3	4
(b) Late	1	3	4
Totals	70	83	153

The following two cases are typical examples of spontaneous recovery.

CASE 1—L. M., a boy aged 5 years, was first seen Feb. 21, 1927, the mother having noted that the child's body was covered with black and blue spots. Examination of the blood showed no anemia, the platelets numbered 10,000, the bleeding time was twenty-five minutes and there was no clot retraction. The child's condition was otherwise unaffected. During the following three months there was a decrease in the number of platelets, which then returned to normal, and the purpuric manifestations disappeared. There has been no recurrence.

CASE 2—D. W., a boy aged 13 years, was admitted to the service of Dr. M. H. Bass July 22, 1935. He was brought from a camp in Maine because of epistaxis and the presence of numerous ecchymoses and purpura scattered over the skin and mucous membranes. Examination of the blood showed hemoglobin 65 per cent, red cells 4,300,000, white cells 10,000, platelets 50,000, a differential count of nonsegmented neutrophils 5 per cent, segmented neutrophils 56 per cent, eosinophils 4 per cent, lymphocytes 30 per cent and monocytes 4 per cent, bleeding time nine minutes, coagulation time fourteen minutes, capillary resistance reaction positive and no clot retraction.

Within a week the purpura began to fade and the patient made a complete spontaneous recovery.

According to Cause.—In taking the histories in these cases special inquiries were made with respect to infection and the taking of drugs or food as possible causes.

Infection may incite an attack of purpura, especially in children, purpura may also appear during the convalescent period. It was associated with infection in eleven children and in one adult 24 years of age. In four cases the picture resembled infectious mononucleosis and one adult had purpura during the course of infectious mononucleosis. Cases of this kind were reported by Minot,<sup>3</sup> they may offer some difficulty in differentiation from leukemia. The following case is of some interest in this connection.

CASE 3—Acute infectious mononucleosis associated with purpura.

Dr. I. O., aged 24, seen about one week after the onset of illness, complained of sore throat, epistaxis, bleeding gums and widespread purpura more profuse over the lower extremities. The temperature reached 103 F. The pharynx was congested; there were no ulcerations; purpuric spots were scattered over the mucous membranes, and the gums appeared spongy and bleeding. Purpura and ecchymoses were present over the entire body. There was also generalized lymphadenopathy and the spleen was palpable. A diagnosis of leukemia was made on the basis of the clinical examination. Examination of the blood showed hemoglobin 88 per cent, red cells 4,600,000, white cells 1900, platelets 100,000, a differential count of nonsegmented neutrophils 14 per cent, segmented neutrophils 27 per cent, eosinophils 6 per cent, lymphocytes 30 per cent and monocytes 23 per cent, bleeding time normal, and capillary resistance reaction positive.

Purpura occurred in five cases after measles, chicken pox or scarlet fever and in two after an infection of the upper part of the respiratory tract. Purpuric manifestations were severe in one of these cases after measles, during the course of which a cerebral hemorrhage occurred, from which the patient gradually recovered. In two other cases transfusions, indicated because of excessive bleeding, were given. A typical example follows.

CASE 4—Postinfective purpura.

A. P., aged 2 years, was seen with the permission of Dr. B. S. Denzer and Dr. Herbert Gordon on May 6, 1930. After recovery from scarlet fever the child began to bleed from the nose and mouth, and large ecchymoses and purpura appeared all over the body. The condition was complicated by otitis media, which subsequently developed into acute mastoiditis. The child appeared pale and weakly ill. Examination of the blood showed severe anemia (hemoglobin 32 per cent and red cells 1,700,000), white cells 12,200 and platelets 90,000. There was a marked increase in the number of neutrophils, especially of the nonsegmented variety. The bleeding time was over one hour and the bleeding was controlled with difficulty. The coagulation time was forty-five minutes, the capillary resistance reaction was strongly positive, clot retraction was absent. Two transfusions were given on successive days and another small transfusion five days later. The platelet count became normal nine days after the onset of the purpura, and the bleeding time also returned to normal (two minutes). The child was operated on later for the mastoiditis and made an uneventful recovery.

Drug idiosyncrasy was responsible for the development of purpura in sixteen cases, in all of which the disease was at first regarded as idiopathic. Careful questioning, however, revealed that the following drugs had been taken: sedormid five cases, arsphenamine four cases, phenobarbital three cases, quinine two cases (including that of a newborn child), chrysarobin one case and a bismuth preparation one case. With one exception, all patients were adults and recovery was prompt after the drug was discontinued. In the cases of arsphenamine sensitivity transfusions were occasionally necessary.

<sup>3</sup> Minot G. R. Purpura Haemorrhagica with Lymphocytosis. An Acute Type and an Intermittent Menstrual Type. Am. J. M. Sc. 192: 445 (Oct.) 1936.

The following case is of interest in connection with drug idiosyncrasy

CASE 5—Mrs E D, aged 63, admitted to the service of Dr B S Oppenheimer Sept 1, 1935, had noticed the appearance of black and blue spots, particularly on her arms and legs, for ten days. She soon began to suffer from bleeding from the nose and gums, and subsequently there was marked weakness. The patient appeared somewhat pallid, and blood could be seen oozing from her nose, ecchymoses and purpura were present over the entire body. There were moderately severe secondary anemia, marked thrombopenia, leukocytosis and polynucleosis, the bleeding time was twenty minutes and the capillary resistance reaction strongly positive, there was no clot retraction.

On admission to the hospital inquiry was made as to the use of drugs, and the patient stated that since the death of her husband she had become nervous and irritable and had been unable to sleep. She had been advised to take sedormid. This was taken every night for two weeks prior to admission to the hospital. Recovery was rapid after the drug was discontinued.

Food allergy seemed to play no role in cases of thrombopenic purpura. A diet rich in vitamins and with a high protein and high fat content was suggested by Kugelmass,<sup>4</sup> but in my experience its employment was not successful in controlling the bleeding or in increasing the platelet count. Food allergy as a factor in thrombopenic purpura as recently referred to by Squier and Madison,<sup>5</sup> did not seem to play a part in this series.

The association of purpura and neoplasm, especially involving the bone marrow, is not common. This occurred in only seven cases. In one case the purpura occurred after the removal of a malignant tumor of the ovary and in two cases was associated with multiple myelomatosis. In another, multiple myeloma became manifest after the removal of the spleen, the condition having previously been regarded as chronic purpura. In a more recent case multiple myeloma was detected early by sternal puncture.

The cases of idiopathic disease, however—both acute and chronic—comprised the majority of the series. No cause could be found in these cases for the diminished number of blood platelets, which is responsible for the bleeding tendency. As the platelets undoubtedly are derived from the fragmentation of the cytoplasm of megakaryocytes, these giant cells should be studied in various forms of purpura. In the majority of cases of thrombopenic purpura the sternal marrow showed a normal or increased number of megakaryocytes.<sup>6</sup> Lawrence and Knutti<sup>7</sup> found a marked diminution in some cases, and in my experience this megakaryocytopenia in the bone marrow appeared to be of bad prognostic import. Zitzmann<sup>8</sup> applied the term megakaryophthisis to this scarcity of giant cells.

Weakness in maturation or fragmentation of megakaryocytes may be considered an important factor in the pathogenesis of the disease. Willi<sup>9</sup> reported diminished platelet formation in smears of sternal bone marrow in cases of purpura. I have confirmed this

observation. The functions of the spleen in inhibiting, possibly by means of a hormone, this platelet formation, according to Frank,<sup>10</sup> and in destroying or removing the platelets from the blood, according to Kaznelson,<sup>11</sup> are also of great importance. The former factor is possibly of greater importance, as it is unusual to find a considerable increase of platelets in splenic smears in cases of purpura. In some cases the spleen may act as an aggravating factor and its removal restores the platelets to normal qualitatively, although not quantitatively in some cases, according to Brill and Rosenthal.<sup>12</sup>

*According to Course*—The course of thrombopenic purpura may be either acute or chronic. The symptoms may be mild or severe in both types, so that it is sometimes difficult to predict at the outset whether the disease is of the acute or chronic form.

*Acute Disease* A review of cases of acute disease shows them to fall into three groups. The first group represents the acute type in children and occasionally in adults, idiopathic or occasionally associated with some form of infection, resembling glandular fever, or occurring after the subsidence of an infection or a manifestation of drug idiosyncrasy. Recovery is spontaneous in these cases (fifty-eight). The second group constitutes the beginning of a chronic type, it usually starts as a mild form. As treatment continues—with either transfusions or snake venom—recovery fails to occur and there is a persistence of symptoms associated with thrombopenia. The disease may become severe during early observation, so that more radical measures, such as splenectomy, may have to be advised. That procedure may account for some of the good results obtained in the treatment of so-called acute disease. In the third group are cases of the markedly acute type, with severe bleeding and rapid development of anemia. The patient becomes somewhat toxic, and leukocytosis and polynucleosis develop. Hemorrhages may be found in the fundi, these being unusual in benign forms of purpura. The cases run a rapidly fatal course and survival does not occur if splenectomy is done. Postmortem examination shows vascular changes with generalized small intravascular thrombi. More detailed reports of this group were presented by Baehr, Klemperer and Schiffrin<sup>13</sup> and by Friedberg and Gross.<sup>14</sup> Another fatal form of acute purpura is associated with a pronounced diminution in the number of megakaryocytes ("megakaryophthisis") in the bone marrow. In one case of this type splenectomy was performed without influencing the bleeding, which became more profuse. In this case and in two others of this type intracutaneous injections of snake venom induced violent reactions. Fortunately the acute form is not frequent, but its recognition is important from a prognostic standpoint.

*Chronic Disease* Cases of this type formed the larger group which required treatment. In some of these the condition was mild and required no special therapy. In one patient the disease was discovered accidentally. She was admitted to the hospital for dia-

betes, but ecchymotic spots were found on the lower extremities. The bleeding time was normal and clot retraction was present, but the platelets were found to be diminished to 90,000. Since then she has had mild episodes of bleeding.

In seventy-two cases of chronic disease the symptoms were somewhat more severe. In some of these blood transfusions were required, and in forty-three splenectomy was performed because of persistence of bleeding or repeated exacerbations. It has been my custom to advise splenectomy in all cases of chronic disease because it may be dangerous to temporize. This is brought out in the following case.

CASE 6—L. P., a Negro aged 42, admitted to the Harlem Hospital Jan 18, 1932, stated that he had had blood spots on the skin ever since he was 10 months old. He had previously been admitted to other hospitals and had been advised to have his spleen removed. On this admission he complained of severe headache, he was drowsy and only at times responded to questions. Ecchymoses and purpura were present. There was considerable rigidity of the neck. He died nine days after admission. His blood picture was typical of thrombopenic purpura. There was no doubt that cerebral hemorrhage was responsible for his death.

A recurrent type of purpura was present in three cases of chronic disease. Symptoms occurred when thrombopenia developed. Severe attacks of bleeding occurred in one case and splenectomy had to be performed. Up to the present time this patient has been free of purpura.

#### TREATMENT

Except for splenectomy, the treatment of thrombopenic purpura is, on the whole, unsatisfactory—if one excludes the form occurring in children and the acute form in some adults. It has been my experience, as previously stated, that the incidence of spontaneous recovery from acute disease of idiopathic or infectious type and especially from that due to drug idiosyncrasy is considerable (38 per cent). As one reviews the various reports of successful medical treatment of purpura, one notes that conclusions as to certain forms of therapy are usually based on a few cases, which are likely to be in instances of this particular group. I have noted that these so-called successful remedies usually fail to cure chronic purpura. My experience coincides with that of Vaughan,<sup>15</sup> who tried various therapeutic agents, including ascorbic acid (intravenously and orally), roentgen irradiation to the spleen and citrin (so-called vitamin P of Szent-Gyorgyi) in a case of chronic purpura, without success.

Some of the suggested means of treatment employed for thrombopenic purpura will now be discussed.

1 *Ascorbic Acid*—In the use of vitamin C for purpura, Engelkes,<sup>16</sup> Vogt<sup>17</sup> and Lorenz<sup>18</sup> obtained good results in apparently acute disease, whereas in the cases of chronic disease reported by Davidson,<sup>19</sup> Wright and Lilienfeld<sup>20</sup> and Stephens and Hawley<sup>21</sup> no effect

was noted. My own observations based on the study of ten cases of chronic disease, indicate practically no improvement from this form of treatment. Finkle<sup>22</sup> found no evidence of vitamin C deficiency in chronic purpura.

2 *Sesame Oil or Fat-Soluble T Substance*—According to Schiff and Hirschberger,<sup>23</sup> sesame oil increases the number of circulating blood platelets. I was, however, unable to confirm this observation. Sherman<sup>24</sup> also has recently employed it in ten cases of chronic purpura, without success. No effect on either symptoms or blood platelets resulted from its use.

3 *Liver Extract*—This has an exceptionally good effect on thrombopenia in pernicious anemia, for this reason its use has been suggested in cases of purpura. Satisfactory results have been reported for acute disease, but Witts<sup>25</sup> obtained no satisfactory results in five cases of chronic disease.

4 *Parathyroid Extract*—Lowenburg and Ginsburg<sup>26</sup> reported good effects in two children following the injection of parathyroid extract. Mathewson and Cameron<sup>27</sup> failed to obtain similar results with this type of treatment. In five cases of chronic and two of acute disease in the present series, no beneficial effect on the bleeding tendency or the platelet count was noted.

5 *Blood Transfusion*—This is of great importance in the presence of severe symptoms. It is thus possible to tide patients over a critical period until splenectomy can be performed. It may be of value for children with acute disease, and in such instances recovery may be hastened. On the other hand, the use of repeated small transfusions in chronic disease has practically no effect on its course.

6 *Roentgen Irradiation*—Results of treatment with this agent have been summarized by Vaughan,<sup>15</sup> who collected twenty-five cases, mainly of the acute forms, and noted that in many this treatment was beneficial. So-called cure or improvement, however, seemed to occur mainly in acute disease. Mettier, Stone and Purviance<sup>28</sup> reported some success in chronic disease following massive roentgen irradiation of the spleen. There was a marked increase in blood platelets within forty-eight hours to normal or above normal, with relapse occurring later. No improvement from this form of treatment was reported by Jones, Tocantins and Smith<sup>29</sup> (six cases), Davidson<sup>19</sup> (three cases), Vaughan<sup>15</sup> (one case) or Bassen<sup>30</sup> in four cases of the present series. Symptoms became exaggerated in some cases. In one instance reported by Jones and his associates<sup>29</sup> a cerebral hemorrhage occurred during roentgen therapy.

**7 Snake Venom**—In previous studies<sup>1</sup> in this connection, Peck and I found that moccasin venom is of considerable value in the treatment of nonthrombopenic forms of bleeding. In certain cases of acute thrombopenic purpura good results were obtained, not entirely attributable to treatment. Nevertheless, the treatment is ineffective in cases of acute purpura accompanied with fever, leukocytosis and polymucleosis or with megakaryophthisis. Reactions in some cases after intracutaneous injection of venom are violent, and its use by this method is contraindicated. For chronic disease however, especially in patients who refuse to submit to splenectomy, I have found snake venom to be of some therapeutic value.

It may be of prognostic importance also, especially in the selection of cases requiring splenectomy. It has been noted that a reversal from a positive to a negative reaction to intracutaneous injection of snake venom is usually associated with improvement. The persistence of a positive reaction usually indicates the ineffectiveness of venom treatment and, in a small percentage of cases, the possibility of failure to react to splenectomy.

Since the last report<sup>1</sup> was published, additional cases of chronic purpura have confirmed my opinion that in only about 50 per cent of cases does symptomatic improvement follow the use of snake venom. In no case have I found a change in the number of platelets. In only a few has a tendency toward diminution in bleeding time been observed but more frequently I have seen improvement in the condition of capillaries indicated by the capillary resistance test. On the whole, in my opinion, the remedy is to be regarded only as palliative.

**8 Splenectomy**—Recent attempts have been made to weed out cases of acute or apparently chronic disease in which splenectomy is contraindicated. Intracutaneous use of venom and sternal puncture are of considerable value for this purpose. The appearance of a violent reaction from intracutaneous injection of venom, such as excessive hemorrhagic reaction or the appearance of bullae or exaggeration of the purpuric state, may be a definite contraindication to operation. This reaction is found in severe types of acute purpura previously mentioned. A marked diminution of megakaryocytes in the bone marrow is also a definite contraindication to splenectomy.

During the period of observation covered in this report forty-three splenectomies were undertaken, the results being compatible with those previously collected and reported by Eliason and Ferguson,<sup>31</sup> by Giffen<sup>32</sup> and by Wintrobe, Hanrahan and Thomas.<sup>2</sup> Seven of the patients had acute purpura, and of these three died after operation and four recovered. Thirty-six patients had the chronic type. Of these twenty-five remained well and three have improved, there were four postoperative deaths resulting from peritonitis or subphrenic abscess, and four patients died later after a recurrence of symptoms. It is noteworthy that in the last-named cases no accessory spleens were found post mortem and many megakaryocytes were present in the bone marrow. Slight attacks of bleeding or purpura may occur in a few cases within the first year following the operation. In most instances, however, there is complete recovery from symptoms.

The variations in the platelet reactions following splenectomy indicate that there are different factors responsible for the underlying purpura. Clinical and hematologic recovery may take place in 50 per cent of the cases. In a few of these there is a thrombocytolytic factor, as shown by the finding of many platelets in the splenic smears, substantiating Kaznelson's<sup>11</sup> theory. Similar recovery may take place in other cases in which no platelets are found in splenic smears, indicative of an inhibitory factor arising in the spleen, as Frank<sup>10</sup> suggested. In an equally large group clinical recovery occurs but the blood platelets do not return to normal. In such instances a failure of platelet formation associated with an aggravating factor in the spleen must be considered. The number of megakaryocytes in the bone marrow seems to bear no relation to the platelet count after splenectomy.

**9 Ligation of the Splenic Artery**—An operation of this type was performed by Berg<sup>33</sup> on two of my patients, but with no success. In one the purpuric manifestations persisted, although the spleen was found to be completely shrunken when a second operation (splenectomy) had to be done. In the other, with chronic disease, ligation of the splenic artery was ineffective in controlling the bleeding. The patient died before secondary splenectomy could be undertaken. Although my conclusions are based on only two cases, this operation must be considered a hazardous undertaking in the treatment of purpura.

#### COMMENT

From a study of 153 cases it appears that purpura haemorrhagica may be divided into four main groups:

1 Acute purpura, idiopathic or associated with infection or a postinfectious state or with drug idiosyncrasy followed by recovery, occurring mainly in children. Patients (fifty-eight) with this type have remained well or have shown no tendency to recurrence. Good results are obtained in this group with all forms of therapy. It is particularly desirable to refrain from splenectomy in children until there is definite proof that the condition is chronic.

2 Acute purpura, of severe form, especially if associated with fever and leukocytosis. In this condition hemorrhages in the fundi and occasional cerebral hemorrhages may occur. This type is usually refractory to all forms of treatment and may show severe reactions from either intracutaneous or subcutaneous injections of snake venom. Splenectomy should be avoided if diagnosis of the underlying toxic condition resulting in intravascular thromboses is suspected.

3 Megakaryophthisis, or diminution of giant cells in the bone marrow. This type is usually acute and responds to neither medical nor surgical treatment. The reaction to intracutaneous injection of venom is severe.

4 Chronic purpura. This type presents marked variations with respect to severity of symptoms, number of blood platelets and number of megakaryocytes in the bone marrow, these may vary in number, namely from 11 to 500 per cubic millimeter. It may also be refractory to most forms of medical treatment and only in a certain number of cases may show symptomatic improvement from the use of snake venom. Symptoms may become severe, necessitating splenectomy. In the majority of cases the outcome may be predicted on the basis of the reaction to intracutaneous venom. Good

results are also generally obtained in cases in which a persistently positive venom reaction is followed by splenectomy and a small percentage of patients recover from the operation but continue to show purpuric symptoms, at times severe

#### SUMMARY

One hundred and fifty-three cases of purpura haemorrhagica have been classified, and the importance of age, causation and especially the course of the disease was observed

A high incidence (38 per cent) of spontaneous recovery is noted in acute disease

At present no medical treatment can be regarded as specific. Snake venom and blood transfusions are the only acceptable means of palliative treatment for chronic purpura

Splenectomy is the curative form of treatment in the majority of cases of chronic purpura, it is contraindicated in some of the acute forms

### THE USE OF CONCENTRATED LIVER EXTRACTS IN PERNICIOUS ANEMIA

A SURVEY OF THE MAINTENANCE TREATMENT OF ONE HUNDRED AND SEVENTY-SIX PATIENTS UNDER CONTINUOUS OBSERVATION FOR FROM SIX MONTHS TO SIX AND A HALF YEARS

WILLIAM P. MURPHY, M.D.

AND

ISABEL HOWARD

BOSTON

The problem of maintaining, over long periods, normal erythrocyte levels in patients with pernicious anemia is one which presents itself to every physician who has such a patient to treat. In the larger hospitals and medical centers many data concerning this problem have been assembled, and from time to time some of these have been published.

Since the purpose of this paper is to present the results of maintenance treatment of the patient with pernicious anemia by parenteral injection of liver extracts over relatively long periods, perhaps a fairly comprehensive review of the literature pertaining to the results obtained by this means will be of value. It was pointed out in the early reports<sup>1</sup> of the use of intramuscular injections of liver extract that observation over long periods is necessary in order to establish the average maintenance dose. Six months may be considered the shortest period over which patients must be observed in order that the data may be of value, for shorter periods are likely to be too greatly influenced by the quantity of anti-pernicious anemia substance administered during initial treatment. Data assembled from published work which most nearly conform to this principle are presented in table 1.

From a consideration of table 1 it is apparent that published data concerning the value of liver extract for parenteral use in the maintenance of normal erythrocyte levels is practically limited to those extracts prepared by one company. The data presented with regard

to the other extracts are incomplete in one or another detail necessary for proper evaluation of their maintenance value. This is particularly true of those extracts of foreign make for which data are lacking either as to the amount of whole liver from which the extract is prepared or as to the level at which the erythrocytes were maintained. The data presented by Isaacs and his collaborators<sup>2</sup> are not clear in respect to either condition, although these authors apparently considered a normal erythrocyte level to be between 4,000,000 and 4,500,000 cells per cubic millimeter. There is practically universal agreement in authoritative data in the literature that an erythrocyte level of about 5,000,000 cells per cubic millimeter is satisfactory for purposes of maintenance, and furthermore maintenance at levels distinctly below this cannot be considered comparable to maintenance at or about 5,000,000, for distinctly more anti-pernicious anemia substance is required to maintain the higher levels. It is also rather universally agreed that only by maintenance at or about the 5,000,000 level is it possible to insure the patient the best possible protection against the development of or progression of already existing neural disturbances.

The economic status of the patients included in the group reported by Connery and Goldwater<sup>3</sup> was poor, and since these patients were undoubtedly partaking of a diet deficient in certain of the substances necessary for proper nutrition it is to be expected that a shorter average interval between injections than that observed by us would be necessary for satisfactory maintenance. However, several patients in this group had their injections at four week intervals.

My reports from the Peter Bent Brigham Hospital blood clinic have consistently shown erythrocyte levels to be maintained at or about 5,000,000 cells per cubic millimeter with intramuscular injections of one vial or 3 cc. of a solution of liver extract (Lederle) at intervals between injections of from three and one half to four weeks. A previous report<sup>4</sup> based on observation of a group of patients for from six months to one year showed that similar erythrocyte levels were maintained with injections of one vial or 1 cc. of a more highly concentrated liver extract (Lederle) given at intervals of approximately three weeks. This extract was undoubtedly used too conservatively, since as will be noted later in this paper, the average interval between injections when considered over much longer periods, from six months to three years, is approximately the same as in the case of the 3 cc. concentrate, or between three and four weeks. There is little doubt that the longer the period of maintenance treatment the more accurate will be the data available for evaluation of the amount of anti-pernicious anemia substance present. Hartfall<sup>5</sup> recently recorded an interval of four weeks between injections of one vial, or 1 cc. of liver extract (Lederle). Hartfall's period of observation was from three to eleven months.

An effort has been made by a committee appointed for revision of the United States Pharmacopeia to rate the various manufactured substitutes for whole liver

According to their anti-pernicious anemia potency, to be expressed in terms of units. A unit is defined as that amount of material which when given daily (during the period of initial treatment when the blood is in relapse) will produce a satisfactory hemopoietic response. On the basis of tests carried out according to the stipulations of this committee, the two extracts which have been used by us for determining the maintenance value as reported in this paper have received ratings of 10 units per vial for the 3 cc preparation and of 15 units per vial for the 1 cc more concentrated one. A vial of each of these extracts is derived from 100 Gm of whole liver. When the preparations are considered on the basis of the committee's rating, one is led to believe that there is a difference in their efficiency, so far as their ability to produce a satisfactory hemopoietic response during relapse of the blood is concerned. The advantage is in favor of the 1 cc concentrate, one vial of which should supply sufficient anti-pernicious anemia substance for fifteen days, whereas a vial of the 3 cc material is sufficient for ten

who have been treated with the 3 cc concentrated extract (Lederle). Treatment of this group has continued for from six months to six and one-half years. The second group includes thirty-one clinic patients who have received the 1 cc concentrate (Lederle) for from six months to three years. The patients in these two groups have been essentially regular in their response and faithfulness to treatment. They have, however, had the usual complications which may be expected in a group of patients of their age with pernicious anemia.

The third group includes twelve clinic patients who either had complications known definitely to influence their requirement of anti-pernicious anemia substance, such as myxedema, severe arthritis or acromegaly, or were not faithful to their treatment.

Table 2 shows the results obtained in the first group, who received at the intervals shown one vial of the 3 cc concentrate, prepared from 100 Gm of liver and with an anti-pernicious anemia potency of 10 U S P units.

\* Prepared from Eli Lilly & Co. and Parke Davis & Co. powdered liver extract for peroral use.

days only. Although the tests of the maintenance value of these two extracts reported herein do not confirm the difference in the unit rating reported by the committee, the fact that the 1 cc concentrate has by it received the higher value supports our belief that the anti-pernicious anemia value of the 1 cc extract is at least as great as that of the 3 cc extract.

In assembling the data for this report we decided to consider erythrocyte levels of 4,500,000 cells per cubic millimeter as the lower limit for inclusion in the period of maintenance treatment. That is, after initial treatment of the patient during relapse of the blood, intensive therapy was continued until the erythrocyte level reached 4,500,000 after which it was considered that the period of maintenance had begun.

One hundred and seventy-six patients were included in the entire survey, and the observations were made over periods varying from a minimum of six months up to six and one-half years. In all instances the extract has been given at intervals which have been determined as the most satisfactory for each individual patient.

The series of patients has been divided into three groups. The first group includes 133 clinic patients

Table 3 is similar to table 2, except that the patients received at the intervals shown one vial of the 1 cc concentrate derived from 100 Gm of liver and with an anti-pernicious anemia potency of 15 U S P units.

From a comparison of tables 2 and 3 it is obvious that the two extracts are approximately equal in their ability to maintain average normal erythrocyte levels.

For further analysis of the data obtained in these two groups of patients, table 4 has been arranged to show the dispersion of treatments by means of one vial of either extract through intervals from one week up to seven or eight weeks.

From an analysis of the data presented it may be seen that one vial of either the 1 or the 3 cc liver extract contains sufficient anti-pernicious anemia substance to maintain the blood of the average patient in a hospital outpatient clinic for from three to four weeks in a normal state. As shown in table 4, over 60 per cent of the patients treated with the 3 cc extract have received injections of one vial at intervals of from three to five weeks, and of those treated with the 1 cc extract over 50 per cent have received one vial at the same intervals. In these two groups of patients there has not been at any time a marked drop below the average erythrocyte level of about 5,000,000 cells, as shown in tables 2 and 3. In a rare instance the count

7 United States Pharmacopeia Anti Anemia Preparations Advisory Board Report on Liver Products New England J Med 218 620 (April 7) 1938

has dropped for brief periods slightly below this desired level because of the occurrence of an acute infection, extraction of a tooth or some other complication which might favor the need for amounts of anti-pernicious anemia substance greater than that just necessary for maintenance at or about 5,000,000 cells per cubic millimeter. That such a drop has occurred only rarely in this rather large group of patients observed for relatively long periods is due to the fact that an effort

TABLE 2—Intervals Between Injections of One Vial or 3 Cc. of Liver Extract for the Maintenance of Normal Erythrocyte Levels in 133 Patients with Pernicious Anemia

Number of Patients	Duration of Maintenance Weeks	Interval Between Injections, Weeks	Average Erythrocyte Count Millions
15	26-52	4.3	5.10
20	53-101	9	5.11
19	102-156	3.2	4.98
16	157-208	3	4.99
22	209-260	3.6	4.90
40	261-312	1.9	5.01
2	313-361	3.4	4.95

has been made to give constantly amounts of anti-pernicious anemia substance greater than that just necessary to maintain the 5,000,000 level.

Except for the complications which have occurred in association with the pernicious anemia, as previously reported,<sup>8</sup> the patients have remained in excellent health, have usually been able to carry on their work, whatever its nature, and have experienced complete arrest of progression of neural disturbances which may have been present when treatment was started. In no case have neural disturbances developed during the adequate regimen of treatment shown.

It has been pointed out in previous reports from this hospital<sup>9</sup> that although some patients may be maintained in a satisfactory state of health while receiving injections of one vial of either of these extracts at intervals greater than four weeks, unless they are so situated that they may be closely followed, with erythrocyte counts at frequent intervals, it is best to give injections

TABLE 3—Intervals Between Injections of One Vial, or 1 Cc. of Liver Extract for the Maintenance of Normal Erythrocyte Levels in Thirty-One Patients with Pernicious Anemia

Number of Patients	Duration of Maintenance Weeks	Interval Between Injections, Weeks	Average Erythrocyte Count Millions
10	26-52	3.3	5.10
4	53-101	3.9	5.26
15	102-156	3.2	5.18
2	157-208	3.9	5.21

at shorter intervals in order to insure an adequate supply of anti-pernicious anemia substance at all times. It is well to reemphasize the well established fact that each patient presents an individual problem in respect to the determination of the amount of anti-pernicious anemia substance necessary to maintain the most satisfactory state of health. The amount necessary is determined on the basis of erythrocyte counts at intervals determined by the trend of the erythrocyte levels on several suc-

cessive counts and of the patient's physical condition, with particular reference to the amount of neural disturbance observed, if present.

Some difference of opinion exists in regard to the value of liver or effective substitutes in the prevention and arrest of the neural disturbances occurring in pernicious anemia. This question has been discussed elsewhere<sup>10</sup> in considerable detail so need not be considered in detail here. An analysis of the literature concerning this question indicates that the general consensus bears out our belief that the use of sufficient anti-pernicious anemia substance to maintain the blood at all times in a normal state with 5,000,000 or more erythrocytes per cubic millimeter will prevent the development of neural difficulties, that it will invariably arrest their progress if present when treatment is started and that improvement in the evidences of neural disturbance will occur in all cases. The degree of improvement will depend on the duration and extent of the damage present before adequate therapy is established. The more pessimistic reports have invariably dealt with groups of patients who have received insufficient treatment to maintain a normal condition of the blood, not commonly because of the use of inadequate amounts of peroral liver extract.

TABLE 4—The Actual Intervals Between Injections for the Patients in Tables 2 and 3

3 Cc. Concentrate		Interval Between Injections, Weeks	1 Cc. Concentrate	
Number of Patients	Percentage of Group		Number of Patients	Percentage of Group
1	0.7	1.2	1	3.2
22	16.5	2.3	9	29.0
50	7.6	3.4	10	37.2
2	2.1	4.5	6	19.4
17	12.8	5.6	2	6.0
4	3.1	6.7	3	9.1
4	3.1	7.8		

It has been suggested recently, but without evidence to support the suggestion, that the more concentrated and refined liver extracts lack some substance or substances which are present in whole liver or the less refined extracts that are necessary for the best results in prevention or improvement of neural disturbances, and that the more concentrated extracts may therefore be less effective than the cruder extracts for this purpose. Although it is possible that such an extract might be prepared in the chemical laboratory by fractional partition of the substances known to be effective in the treatment of pernicious anemia, our experience over many years with whole liver and liver extracts has shown no less effectiveness in this regard in the highly refined and concentrated 1 cc extract than in the cruder extracts or in whole liver. In fact the most striking and complete prevention or arrest of neural damage has been observed in those patients who have received the more concentrated extracts. This is no doubt due to the more intensive treatment which these patients have received because of the ease of administration and the inexpensiveness of treatment, both of which have made the results the most complete and satisfactory of any obtained by the various means available. Arrest and improvement of neural disturbances have been as striking in patients treated with the 1 cc concentrate as in the group treated with the 3 cc extract.

9 Murphy W. P. Rational Treatment of the Anemic Patient. *Ann. Int. Med.* 7: 939 (Feb.) 1934.

10 Murphy, W. P. *Anemia in Practice*. Philadelphia: W. B. Saunders Company.

The twelve patients composing the third clinic group have so far been left out of the discussion because their condition or treatment has been unusual in some respect. A detailed discussion of this group need not be included in this paper, but brief mention of several cases may be of interest. Three members of this group have myxedema in association with the pernicious anemia, and in each the blood has been maintained in a normal state by the use of somewhat greater than average amounts of extract, together with thyroid and iron medication. One patient had acromegaly with glycosuria, hypertension and cholelithiasis but in spite of this was maintained with little difficulty in fairly satisfactory condition for several years, until death occurred from pneumonia. One other patient with typical evidence of pernicious anemia who was not included in the group is of interest only as a curiosity. Since return of her blood to a normal state following treatment during relapse with extract derived from 1,100 Gm of liver, she has maintained a normal erythrocyte level during eight years without further therapy. This case will be reported in detail elsewhere. It has been impossible to maintain the blood of one of this group of patients in a normal state with injections of one vial, or 3 cc, of extract at weekly intervals, in spite of the fact that there is no demonstrable reason for a need for unusual amounts of extract except that her dietary intake is deficient in some respects. No doubt larger amounts of extract would produce the desired result although she has remained in excellent health in spite of a subnormal erythrocyte count. Several patients included in this group have failed to follow up their treatment continuously and so have failed to maintain their blood in satisfactory condition.

It is possible to determine from the data presented the average amount of anti-pernicious anemia substance received by each group and each patient during their course of treatment.

For patients treated with the 3 cc extract a total of 19,212 cc (6,404 vials of 3 cc capacity) derived from 640,400 Gm of liver has been administered during a total of 23,766 weeks. Each patient has therefore received weekly an average of 0.81 cc of extract derived from 26.9 Gm of whole liver.

TABLE 5—Amount of Anti-Pernicious Anemia Substance Required at Various Ages

Number of Patients	Age Years	Average Interval Between Injections, Weeks	Average Erythrocyte Count Millions
5	30-39	4.1	5.25
26	40-49	3.9	5.16
41	50-59	3.6	5.09
65	60-69	3.7	5.03
26	70-79	3.5	4.87
1	80-89	2.4	4.59

Similar figures for the patients receiving the 1 cc concentrate show that 883 cc of extract derived from 88,300 Gm of liver has been given over a total of 2,950 weeks. Each patient has therefore received weekly an average of 0.3 cc of the more concentrated extract derived from 29.9 Gm of whole liver.

Were one to apply the method of the Committee for Revision of the Pharmacopeia in determining the unit rating of each extract for maintenance, each of these would be found to contain between 20 and 25 units of anti-pernicious anemia potency. At any rate it is obvious that extremely small quantities of these extracts are needed for maintenance, because of which injections

of one vial may be used to advantage at intervals of about three and one-half weeks in place of more frequent or larger doses of the less highly concentrated ones. This is particularly true of the more highly concentrated 1 cc material. For the patient this means less discomfort, less inconvenience and less expense than is possible with the use of extracts of lower concentration and potency, and except for the remnant in a few of disturbances due to neural damage and the disturbances caused by complications the patients have remained in an excellent state of health.

The question as to what influence the age of the patient may have on the amount of anti-pernicious

TABLE 6—Amount of Anti-Pernicious Anemia Substance Required According to the Sex of the Patient

Number of Patients	Average Interval Between Injections, Weeks	Average Erythrocyte Count Millions
100 women	3.6	5.06
64 men	3.8	5.23

anemia substance necessary for maintenance has been raised and is answered according to our experience by the data presented in table 5. In this table the average interval between injections of one vial of either liver extract for ages by decades is shown for the 164 patients included in groups 1 and 2. A slightly greater amount of anti-pernicious anemia substance has been necessary to maintain a somewhat lower average erythrocyte level in those patients over 70 years of age than in those below this age. This difference is not striking or conclusive evidence that age in itself has a definite bearing on the amount of anti-pernicious anemia substance necessary. Arteriosclerotic changes and other complications which influence the need for this substance are common in the older age group. The one patient above the age of 80 is now 86 after six years of treatment, has marked hypertension, myocarditis and generalized arteriosclerosis and yet remains in fairly satisfactory health.

The relative average requirements of anti-pernicious anemia substance for men and women are shown in table 6.

Again the difference in the amount of anti-pernicious anemia substance necessary for maintenance of the two groups is too slight to be of significance.

#### SUMMARY

One hundred and seventy-six clinic patients have been treated with intramuscular injections of liver extract during periods ranging from six months to six and one-half years.

Of these, 133 have received an injection of one vial, or 3 cc, of liver extract (Lederle) at average intervals of 3.7 weeks in order to maintain the erythrocyte count continuously at a level of about 5,000,000 cells per cubic millimeter.

Thirty-one of the group have received an injection of a vial, or 1 cc, of a more highly concentrated liver extract (Lederle) at average intervals of 3.6 weeks in order to maintain the erythrocyte count continuously at a level of about 5,000,000 cells per cubic millimeter.

Neither age nor sex definitely influences the amount of anti-pernicious anemia substance necessary for maintenance.

It has been demonstrated that the intramuscular injection of 1 cc of liver extract, containing 15 U S P units of anti-pernicious anemia potency (Lederle),

administered at intervals averaging approximately three and one-half weeks is sufficient to maintain a normal state of the blood and to prevent or arrest neural damage. This method of therapy is of particular value in respect to prevention and arrest of disturbances caused by neural damage.

Treatment should be individualized according to each patient's needs, determined on the basis of the patient's clinical condition and erythrocyte counts made at desirable intervals.

## THE TREATMENT OF IRON DEFICIENCY ANEMIAS

W M FOWLER, M D  
AND  
ADELAIDE P BARLER PH D  
IOWA CITY

The results obtained by the administration of iron to patients with certain types of secondary anemia are nearly as spectacular in many instances as the effect of liver extract in pernicious anemia. The rapid increase in hemoglobin which follows its use has served to focus attention on iron therapy but has also emphasized the fact that many problems concerning the mechanism of its action are still unsolved. Iron has been raised to the status of a specific remedy, but this has been accomplished more by the better selection of cases for its use than by the introduction of more efficacious preparations. Its routine and somewhat perfunctory use in all cases of secondary anemia has been superseded by the more rational administration of adequate amounts in properly selected cases.

It is well recognized that insufficient iron for hemoglobin formation will lead to anemia of the hypochromic type, characterized by microcytosis and hypochromia of the individual cells, by a low color and volume index and by a low mean corpuscular hemoglobin concentration. This is frequently referred to as iron deficiency anemia. The most common form results from chronic hemorrhage. It occurs whenever the prolonged loss of iron, in the form of hemoglobin, is more rapid than its replenishment from the dietary intake and is encountered most frequently in cases of peptic ulcer, hemorrhoids and menorrhagia.

The cause of idiopathic hypochromic anemia is fundamentally the same.<sup>1</sup> In this syndrome the blood loss is frequently unrecognized menorrhagia, so that no history of excessive bleeding can be obtained from the patient. The achlorhydria or hypochlorhydria, which is present in practically all patients, interferes with the proper absorption of iron from the food,<sup>2</sup> so that a blood loss which might otherwise be of little significance assumes increased importance. In some instances even the normal menstrual blood loss seems to be sufficient to produce an iron deficiency when there

is a disturbed gastric secretion. The hypochromic anemia of pregnancy appears to be identical with the idiopathic form except for the manner in which the iron stores are depleted.<sup>3</sup> In cases in which the anemia is associated with pregnancy the maternal iron supplies are depleted by the fetal requirements rather than by hemorrhage, while the achlorhydria prevents their replacement. In many instances the anemia persists after a single pregnancy or after repeated pregnancy, and then presents features characteristic of the idiopathic form. A diet deficient in iron may lead to the same hypochromic, iron deficiency type of anemia. In our experience this is more frequently a contributing factor than the sole cause of severe anemia. A diet with a low iron content is of greater significance when the patient has achlorhydria, and as a result it frequently plays a part in the development of idiopathic hypochromic anemia and the hypochromic anemia of pregnancy. The restricted diet and excessive administration of alkalis<sup>4</sup> to patients with peptic ulcer interfere with the replenishment of their iron stores.

It is with these types of iron deficiency anemia regardless of how they are produced, that iron therapy is particularly effective and the recognition and classification of these anemias as a separate group with a common mode of therapy has been a distinct advance.

A second factor which has tended to produce a more satisfactory and more uniform response to iron therapy in recent years has been the more general administration of adequate amounts of iron. There has been much discussion as to the most efficacious iron preparation and the amount of iron to be administered, but the present consensus, based on extensive clinical experience, favors the use of inorganic iron in large doses. The reason for the greater effectiveness of excessive amounts of iron as compared with smaller amounts has not been satisfactorily explained<sup>5</sup> and the answer cannot be given until the mode of action of the iron has been ascertained. It has been assumed, since we are dealing with a group of anemias which are apparently due to an iron deficiency, that the administered iron acts solely as a replacement therapy. A further assumption has been that large amounts of iron must be administered in order to insure the absorption of a sufficient amount to replace the deficiency. Recent experimentation has cast some doubt on the truth of these assumptions.

In order to ascertain the amount of iron which is retained and utilized, a series of detailed balance studies were carried out in which the iron intake, the iron excretion and the hemoglobin regeneration were accurately studied. Iron in the form of iron and ammonium citrates, 3 Gm daily, was administered orally to ten patients with hypochromic anemia.<sup>6</sup> This dose represents the equivalent of 500 mg of metallic iron and is only half of the commonly recommended dose. It was found that 32.6 per cent of the administered iron was retained, representing a daily retention of from 72 to 368 mg. In eight of the patients who were followed over a sufficiently long period for the hemoglobin response to be of significance (table 1), it was found that approximately 2 per cent of the administered iron was used in the formation of hemo-

globin and that of the iron actually retained only 6.3 per cent was used in hemoglobin formation. In five of these patients the hemoglobin response was between 0.09 and 0.117 Gm per hundred cubic centimeters of blood daily, and in three it was below this amount. There was no correlation between the amount of iron retained and the rapidity of hemoglobin formation. The optimal hemoglobin response has been set arbitrarily as a rise of 1 per cent daily when the initial level is below 50 per cent of normal,<sup>7</sup> but the response obtained in these five patients might be considered satisfactory even though the amount of iron and ammonium citrates was only half the recommended dose.

Similar balance studies were carried out on patients receiving 1 Gm of iron and ammonium citrates daily, or from 160 to 180 mg of metallic iron.<sup>8</sup> The daily retention of iron varied from 26 to 114 mg a day, and for the entire group 26.6 per cent of the administered iron was retained. In three patients under observation for eighteen or more days the hemoglobin increase ranged from 0.08 to 0.15 Gm daily and the iron retention from 42.6 to 82.8 mg (table 2). This retention is greatly in excess of the amount of iron actually used in hemoglobin formation. Moore<sup>9</sup> has shown that the iron content of the blood plasma is increased after the oral administration of iron and that this is the method of transport within the body. Where this excess iron is stored has not been definitely proved, although it presumably goes to the liver, spleen and other reticulo-endothelial tissues.<sup>10</sup> That such large amounts of iron are retained is contrary to the common belief, but this has been substantiated by other investigators. Brock and Hunter<sup>11</sup> found a retention of from 4 per cent to 32 per cent of the intake when varying amounts of several different iron preparations were administered. Reimann and Fritsch<sup>12</sup> obtained as high as 53.8 per cent retention from small doses of ferrous chloride.

TABLE 1—Iron Retention and Utilization When 3 Gm of Iron and Ammonium Citrates Was Given Daily

Patient	Average Daily Iron Retention, Mg	Iron Retained per Cent	Average Daily Hemoglobin Increase Gm	Iron Utilized per Cent
1	308.0	71.3	0.037	1.09
2	266.9	51.4	0.056	1.62
3	261.2	50.5	0.117	3.42
4	225.2	43.6	0.117	3.41
5	18.0	36.4	0.041	1.20
6	151.0	31.6	0.092	2.90

8	72.6	14.0	0.095	2.77

The lack of correlation between the amount of iron retained and the hemoglobin regeneration, as well as a comparison between the large percentage of iron retained and the small percentage utilized, does not support the idea that iron is acting purely as a form of replacement therapy. The results of the balance

studies also show that the administration of large amounts of iron is not necessary for adequate retention and that the retention of extremely large amounts of iron is not necessary to secure adequate hemoglobin regeneration in all cases.

No correlation was noted between the degree of anemia and the amount of iron retained, and anemic subjects did not retain more than those without anemia.<sup>13</sup> An absence of hydrochloric acid in the gastric contents decreased the absorption of iron from

TABLE 2—Iron Retention and Utilization When 1 Gm of Iron and Ammonium Citrates Was Given Daily

Patient	Average Daily Iron Retention, Mg	Iron Retained per Cent	Average Daily Hemoglobin Increase Gm	Iron Utilized per Cent
1	82.8	45.1	0.151	12.4
2	41.7	27.1	0.082	7.5
3	42.6	23.2	0.100	8.2

the dietary intake, but when large amounts of iron were administered achlorhydria had no effect on the retention of iron or on the regeneration of hemoglobin.<sup>13</sup> The addition of copper to a small dose of iron and ammonium citrates resulted in a diminished retention but an increased utilization of iron, but when copper was added to a larger dose of iron it had no effect.<sup>14</sup> In neither instance was the hemoglobin regeneration more rapid than with iron alone. The addition of an orally administered liver extract to the iron and ammonium citrates had no appreciable effect on either the retention of iron or the rapidity of hemoglobin formation.<sup>14</sup>

The results of these experimental studies on a relatively small group of patients cannot be interpreted as evidence that the administration of large doses of iron is never indicated. It is obvious that sufficient iron must be supplied to form new hemoglobin, and these investigations have shown that this amount can be retained from small doses of iron. The function of the excess iron, which apparently increases the rapidity of the hemoglobin formation, is not clear. It has been shown that small doses of iron will suffice for adequate hemoglobin formation in many patients, whereas with others a large amount must be administered. Heath<sup>7</sup> and Witts<sup>15</sup> have emphasized the fact that patients do not all respond similarly to the same amount of iron, so that an optimal dose, applicable in all cases, cannot be defined. In order to obtain a satisfactory response in all patients it is necessary to give as a routine an amount of iron considerably above that needed by many. The larger amounts are particularly advisable for those who cannot be followed by frequent hemoglobin determinations and also for those with a severe degree of anemia.

The first demonstrable effect of iron therapy is an increase in the number of reticulocytes. The rise is slower and the height of the reticulocyte crisis is lower than in pernicious anemia treated with liver. It has been shown that the increase is inversely proportional to the hemoglobin level and the erythrocyte count at the beginning of treatment.<sup>16</sup> The reticulocytosis will

ordinarily be evident before there is a significant change in the hemoglobin content and this may be used as an indication of whether or not the amount of iron being administered is adequate, but the final and best criterion on which to judge the efficacy of an iron preparation is the hemoglobin response.

Strauss<sup>17</sup> has recommended the following amounts of the commonly used iron preparations: iron and ammonium citrates 6 Gm daily, reduced iron 3 Gm, pills of ferrous carbonate 4 Gm and ferrous sulfate 1 Gm (table 3). Even with these doses the condition is occasionally refractory and still larger amounts are necessary, although in many instances smaller doses will suffice. It has been shown that an amount of iron in divided doses is more effective than the same amount in a single dose.<sup>18</sup> The drug is best given during or immediately after a meal, so as to lessen the gastrointestinal irritation which occasionally accompanies its administration. Even with these precautions a few patients complain of abdominal cramps and diarrhea, and we have encountered a few in whom no preparation, no matter how coated or how administered, can be tolerated. On the whole, the soluble preparations are more apt to cause gastrointestinal symptoms, and

patients with achlorhydria. Ferrous carbonate is given in pills, and it is advisable that they be freshly prepared since oxidation to an insoluble form may occur. Since the pills commonly contain 5 grains (0.3 Gm), it requires twelve or more daily. Ferrous sulfate is given in the form of pills with various types of coating to lessen the irritation. Because of the smaller bulk required they are especially popular, but they have a tendency to cause gastric irritation. Ferrous chloride, which has been shown to give a high percentage of retention and utilization<sup>21</sup> may be given in 0.5 Gm capsules or in solution in a simple syrup. Although it is effective when given in relatively small amount, it is also one of the compounds that are the most irritating to the gastrointestinal tract.<sup>2</sup>

There are on the market innumerable preparations of iron which may be used but none seem to possess a distinct advantage over these common forms. There is no apparent need for the addition of vitamins, liver extract or other metals to a simple iron preparation in the ordinary case, and in our experience the intramuscular administration of iron has not been effective.<sup>1</sup>

#### CONCLUSION

The recent increased popularity of iron in the treatment of certain types of anemia has been brought about more by a better selection of cases for its use than by any improvement in the mode of administration.

Balance studies have shown that large amounts of iron are retained by the body even when relatively small doses are being administered and that a satisfactory hemoglobin response is obtained in many instances with small doses.

The commonly used iron preparations given by mouth are satisfactory without the addition of other metals or other substances.

TABLE 3—Iron Therapy Recommended Doses\*

Drug	Daily Dose Gm	Iron Content Mg
Iron and ammonium citrates	6	1,000
Reduced iron	3	2,700
Pills of ferrous carbonate	4	360
Ferrous sulfate	1	200

\* Strauss<sup>17</sup>

we have given reduced iron with success to many patients who could not tolerate other forms.

The form in which iron is to be administered is of minor significance, and each physician is prone to have a favorite preparation. The effectiveness does not depend on the amount of metallic iron which is being administered, since soluble forms are better utilized than insoluble preparations with the same iron content. Ferrous salts are more efficient than ferric salts,<sup>19</sup> and Wits<sup>20</sup> expressed the opinion that the efficiency of any iron preparation depends on its ability to liberate ferrous ions. From the patient's standpoint the smaller effective dose of the ferrous compounds is a distinct advantage. Iron and ammonium citrates has been one of the most popular preparations in this country and is administered in capsules, in aqueous solution or in syrup. When it is given in solution the teeth must be protected against discoloration by the use of a drinking tube. Reduced iron is less active therapeutically when considered in terms of its metallic iron content, but the actual dose, in bulk, is relatively small and gastrointestinal symptoms are seldom encountered. It is administered in capsules, and the recommended dose contains 2,700 mg of metallic iron as compared with 1,000 mg of iron in the 6 Gm of iron ammonium citrates. Reduced iron acts by the formation of ferrous chloride in the stomach, so that it is somewhat less effective in

#### ABSTRACT OF DISCUSSION

ON PAIERS OF DR ROSENTHAL, DR MURPHY AND ISABEL HOWARD, AND DRS FOWLER AND BARER

DR L W DIGGS, Memphis, Tenn. In the treatment of severe anemia and hemorrhagic diseases and shock due to acute loss of blood, transfusion is the therapeutic procedure of choice. Blood is, however, expensive and volunteer donors are often difficult to obtain. In large charity hospitals unable to purchase blood from professional donors, many patients die from lack of blood. In such institutions the blood bank offers a partial solution of the problem. For several months at the John Gaston Hospital in Memphis a blood bank has been maintained and more than 200 transfusions have been given. There have been an appreciable number of febrile reactions of varying degrees of severity and one sudden death, but in the majority of cases there have been no reactions. Lives have been saved and emergency operations made possible. To have on hand blood of all types for immediate use, from 15 to 20 liters of blood should be stored at all times. With this amount of capital it is necessary to use the blood at the rate of 2 liters a day in order that the oldest blood may be used before hemolysis occurs. My associates and I have used blood as old as 15 days without reaction but prefer to use it within ten days after it is drawn. The labor involved in the collection, culture, storage, matching and dispensing of the blood and the keeping of the records is not to be minimized. We have been dependent on rotating laboratory interns and student nurses for part of our work but do not recommend this system to others, for the material dealt with is too valuable and the skill required too great to be entrusted to inexperienced persons. Some one responsible person should be in charge, preferably a technician.

or a graduate nurse thoroughly trained in bacteriologic methods and in surgical technique. Trained personnel should be available for twenty-four hour duty, for volunteer donors usually come to the hospital after working hours and blood for emergencies is needed at all times. The blood bank is a new development and there is much to be learned about the possibilities and dangers of preserved blood. Perhaps better methods of preservation can be discovered. Before the blood bank can be approved for general use it must be tried out in a number of hospitals and the results critically evaluated.

DR T. W. MADISON, Milwaukee. The problem of pathologic hemorrhage has interested Dr. Squier and me for some time. We have attempted to approach it from the standpoint of both the pathologic and the etiologic mechanisms involved. Cases in which pathologic hemorrhage occurs fall roughly into three groups. First there are those in which hemorrhage is the result of increased capillary permeability, as seen typically in scurvy. Vitamin C deficiency, endocrine disturbances and allergic reactions are the more common causes of the capillary changes. Second there are the cases in which hemorrhage is due to a defect in the mechanism of coagulation of the blood without capillary changes. The two best clinical examples are the bleeding due to prothrombin deficiency in obstructive jaundice and that which occurs in hemophilia. Third there is the large group in which there is a defect in both the capillary permeability and the mechanism of coagulation. Most cases in the third group are instances of what is known clinically as purpura. So far as treatment is concerned, one has to be guided by pathologic and etiologic mechanisms. The use of vitamin C when increased capillary permeability is due to deficiency of that vitamin is of course specific. The fruit juices are more effective than the synthetic vitamin C. Prothrombin deficiency is still best dealt with by blood transfusions, though administration of vitamin K with bile may prove to be a simpler approach. By transfusing at thirty-six to forty-eight hour intervals one can maintain the prothrombin above the critical level in the majority of instances. The problem of the treatment of purpura is by far the most puzzling. In our opinion vitamin deficiency does not enter into the problem of purpura. The matter of infection, as Dr. Rosenthal's statistics have shown, is exceedingly important. Endocrine factors are of importance but difficult to evaluate. It is our belief that the matter of allergic influences is of the greatest importance in certain cases of purpura, both thrombopenic and nonthrombopenic. We like to think of thrombopenic and nonthrombopenic purpura as differing not in kind but in degree. Transfusions remain the most satisfactory means of keeping persons with purpura alive until their bleeding stops. Empirically, splenectomy has furnished a fairly satisfactory means of controlling the curious underlying mechanism and is at times life saving. We have been able to control satisfactorily true thrombocytopenic purpura in a group of cases by the ordinary allergic approach.

DR FRANK J. HECK, Rochester, Minn. While in the main I agree with what Dr. Murphy has said, there are a number of points on which I cannot but disagree. I have never been able to understand the difference in normal counts as presented, for instance, by the work of Wintrobe and the average counts as seen in normal males. Only rarely are normal males with erythrocyte counts of 5,000,000 or above seen. Therefore I do not feel that in the treatment of patients with pernicious anemia physicians can be guided by that criterion. I am perfectly willing for my patients to have, or want them to have, 4,500,000, but in many of them I have been unable to obtain a count of 5,000,000, even after increased intramuscular use of liver extract. Second, the Pharmacopeia Committee has made a distinct advance by setting up unitage, and yet I cannot accept all of the ideas, as I know many physicians cannot. The hardest thing for me to accept is Why does Lederle's 1 cc preparation contain 15 units and the 3 cc preparation made from the same amount of material contain only 10? The other point I should like to bring out is this. It is known that different patients respond differently to the same amount of liver extract and therefore that point must be taken into consideration in determining unitage. I have used intramuscular liver extract particularly Lederle's extensively but my results do not agree with those of Dr. Murphy on this point. I cannot carry my

patients an average of 39 weeks by the use of a single injection of either the 1 or the 3 cc preparation. Whether this is due to climatic or dietetic differences, I cannot explain. As far as improvement in neurologic symptoms is concerned, I agree heartily with Dr. Murphy. It is true that a certain group of patients with advanced combined sclerosis show little improvement. Yet over a period of years, by proper therapy, with both liver extract and physical therapy and exercise, a great majority of these patients can be made into useful citizens. I should like to make a point with regard to the use of various extracts. Until some large institution compares various extracts in a large enough series of cases of disease of the same degree of severity, I do not feel that individual extracts should be emphasized too greatly. I cannot but feel that there may be a point for the less pure extracts.

DR C. B. WRIGHT, Minneapolis. I am in agreement with the last speaker. I see younger men who are relying too much on 1 cc doses of extract and do not carefully study food idiosyncrasy and the question of whether the diet is sufficient. Having started originally on raw liver therapy, I feel that if the patient can take calf's liver without any difficulty he should do so two or three times a week. This is an exceedingly valuable adjunct in the treatment of pernicious anemia. In addition, I give 1 cc of concentrated extract every three weeks as a rule. My experience is that every three weeks is often enough, provided liver is added to the diet, in most cases. I find cases that do not react to this dose and require much more intensive liver therapy. I don't think any available agencies in the handling of these patients should be neglected.

DR RUSSELL L. HADEN, Cleveland. This program was entirely invitational, and each author is interested in every other phase of blood dyscrasia. Transfusion is the common denominator of all treatment. It has been my experience that that is the sheet anchor of treatment of the hemorrhagic diseases. It makes no difference whether transfusion is done by the direct or by the indirect method. In our institution my associates and I do it both ways, and I cannot see any difference in the final results. I went over a fairly large group of cases of thrombopenic purpura from our clinic to see in what percentage we had advised splenectomy. Our figures showed roughly one fourth. Dr. Rosenthal told me his figures were about the same. He has emphasized well that in these younger people one ought to be conservative. Too often spleens have been removed for thrombopenia when the cause of thrombopenia was leukemia. Pernicious anemia is a deficiency disease, due to the lack of something. I do not believe that true pernicious anemia can be separated from the other deficiency diseases. It is the experience of all who have been interested in deficiency diseases that the use of crude extracts is important, as Dr. Wright has said. Dr. Heck has brought up the interesting question of what I once called the geographic variation in the red blood cell count. I have never been able to determine whether it is geographic or technical. I agree with Dr. Murphy that a red blood cell count of 5,000,000 in pernicious anemia is perfectly safe. I am also sure that many patients, as Dr. Heck has said, who do not have a count of 5,000,000 are perfectly safe. I still think the one criterion which can be depended on is the size of the red blood cell, because with a deficiency of the substance that is protected against pernicious anemia the cell gets larger, and this can be detected easily by measurements of volume. I have wondered, in the treatment of pernicious anemia, why the patient is given just enough. After all, liver extract is cheap as compared with the seriousness of the disease. I have given a large dose of liver extract and always have depended on a potent preparation. If a patient comes in without neurologic involvement and follows the physician's advice, it is the physician's fault if a neurologic lesion develops. The reason is that he should have very intensive therapy. I insist that he eat liver as much as possible, at least once a week, as Dr. Wright has emphasized. As I have carried patients five, six, seven and eight years, I have found them to be more difficult to control. One has to depend here entirely on parenteral therapy. With regard to iron therapy, why give a preparation such as reduced iron, in which less than 1 per cent will be used, when there are preparations, such as ferrous sulfate in which, say, 10 per cent is used and which are exceedingly cheap.

DR EDWIN E. OSGOOD, Portland, Ore. Certain practical points with regard to purpura haemorrhagica are worth stressing. Accurate differentiation from the other diseases which may produce the syndrome is the first essential in sound therapy. Transfusion and splenectomy are the most important methods available for the treatment of the disease. I plan to give three or four transfusions in the twenty-four hours preceding the splenectomy and have a typed donor available in the operating room. The same number of transfusions spread over three or four days may not control the bleeding. With milder disease transfusion alone may control the bleeding until spontaneous recovery occurs, but donors should be typed as soon as the diagnosis is made and not after a severe hemorrhage occurs. Another point often overlooked is that the bleeding time is a far more satisfactory routine preoperative criterion than the coagulation time, for purpura haemorrhagica rather than hemophilia is the common cause of excessive bleeding at operation. Adequate therapy in anemia must be based on an accurate diagnosis. This diagnosis should include the degree, the type and the cause of the anemia. Physicians are perhaps more indebted to Dr. Haden than to any one else for reemphasizing the importance of the color, volume and saturation indexes in the classification of anemia for therapeutic purposes. In hypochromic microcytic anemia adequate amounts of inorganic iron, as Dr. Fowler emphasized, will lead to dramatic recovery, but the cause of the chronic hemorrhage usually present should be investigated and treated too. In microcytic anemia adequate amounts of anti-pernicious anemia principle are essential. It is rarely necessary to give the two to the same patient. In normocytic anemia benefit from either iron or liver is rare. Transfusions and removal of the cause are the therapeutic methods of choice. Since neither iron nor liver produces toxic effects in large doses and since too small doses may do harm, I prefer to err on the side of giving too large a dose. The diagnosis of the type and cause of the anemia should be made before treatment is started except in desperately sick patients, because the most difficult cases to diagnose are those in which a little iron and a little liver have been given—just enough to alter the blood picture but not enough to correct the anemia. Dr. Haden made a remark to the effect that, unless patients fail to cooperate, a uniformly good response to adequate amounts of liver can be expected in microcytic anemia. I am sure that he will agree with me, however, that it should be part of the physician's responsibility to educate the patient sufficiently in the nature of the disease so that he will cooperate.

DR HAROLD W. JONES, Philadelphia. I wish to emphasize that for the good of the community county medical societies should control commercial blood banks. "Werthof's disease" is a misnomer, because Werthof was not the first to describe purpura. My experience differs from that of Dr. Rosenthal in two ways. 1. I have not had good results with moccasin venom. 2. A larger percentage of my patients have been either temporarily or permanently benefited by transfusions. Like Dr. Murphy, I use Lederle's liver extract in the treatment of pernicious anemia. My aim is to give one 3 cc dose intramuscularly each month. To maintain the red blood cell count at about 5,000,000 it is necessary to give some patients weekly injections. Since I have used intramuscular injections, none of my properly controlled patients have had symptoms of cord change. For those who already have cord change, I have used fever therapy in addition to large doses of liver extract and vitamin B. Excellent results were obtained. Dr. Haden mentioned the mistake of removing the spleen in patients with leukemia diagnosed as purpura. I have knowledge of one patient with a condition diagnosed as leukemia who actually had essential thrombopenia. No treatment was given and the patient died. In the treatment of idiopathic hypochromic anemia my results have been similar to those of Dr. Fowler. Many patients with a condition formerly diagnosed as secondary anemia and now placed under the heading of hypochromic anemia have not responded to iron or iron and acid until copper was added. A few patients seem to do better with courses of injections of iron and liver extract. Occasionally I have met patients in whom no result was obtained by any form of treatment until some so-called focal infection was removed. Repeated small transfusions seem to be the only method of bringing about satisfactory results in some cases.

DR NATHAN ROSENTHAL, New York. I should like to make a few remarks concerning my own experience. Considerable interest has been shown in blood banks. These have been instituted in three hospitals in New York City, namely Bellevue, Kings County and Mount Sinai. In the last hospital the plan is proving successful, although the period of observation has been rather short. The reactions seem to be not much greater than with fresh citrated blood, namely about 3 per cent have chills. Apparently more reactions, such as those as a result of urticaria, were noted. It is important to note that commercial blood banks are not permitted in New York City. In fact, permission must be obtained from the department of health before this new and, I believe, important addition of the institution may be undertaken. I thank Dr. Madison for his discussion of the purpuric problem. I believe that there are different, distinct types of purpura. The main group is thrombocytopenic purpura. It is undoubtedly a disease of the megakaryocytes. It may be idiopathic and result in recovery, either spontaneously or following splenectomy. It may also be due to known causes, especially drugs—arsphenamine, sedormid (allyl-isopropyl acetyl carbamid), phenobarbital, quinine and, lately, chlorzoxime. After the drug is stopped there is spontaneous recovery. A clear distinction must be made between these forms of purpura and Schoenlein-Henoch purpura. The latter is not a disease of the megakaryocytes and blood platelets but is some peculiar vascular disturbance. It may be of an allergic type. The cause is unknown but, as I have pointed out, definite impairment of the vascular elastic tissue may occur. As a result, the purpura may persist for a long time in the lower extremities as so-called orthostatic purpura. Another form of purpura is known as chronic hereditary thrombasthenia, or pseudohemophilia. This is a somewhat rare condition and is the result, possibly, of a functional disturbance of the platelets although they are not diminished in number. The blood picture in this disease is not constant and it may be discovered only after repeated examination of the patient's blood.

DR WILLIAM P. MURPHY, Boston. This has been one of the most interesting and instructive discussions of the blood dyscrasias that I have had the privilege to attend. There is no form of therapy which is more urgent at times than transfusion and no form the use of which is more widely abused. A transfusion should be carried out with the care of a surgeon but with the skill of a physician. It is almost never necessary to cut down on the vein of either recipient or donor, and this should not be done, particularly in those patients who may be dependent on repeated transfusions for maintenance of life. Transfusions should be performed only by skilled operators. Certainly they should not be turned over to the untrained house staff but should always be done by or under the supervision of one thoroughly skilled both in the preparation for and the technique of giving them. Dr. Fowler's paper interested me particularly for the reason that it emphasizes the need for more careful and complete studies concerning the use of iron as a therapeutic agent. Because of the publication of incomplete studies and at times inaccurate data, there is much confusion in respect to the amount of the various iron salts desirable for best results and the most desirable salt to use. Knowledge in these respects has advanced little beyond that of Dr. Blaud as early as 1832. Greater care should be observed in drawing conclusions as to the comparative value of various doses of the different iron salts, for as yet there is not conclusive evidence that one of several popular salts is effective in distinctly smaller doses than is any of the others. Optimal doses should be given in all instances. Dr. Wright has well emphasized the importance of controlling all the details of the patient's life and therapy for the best results in the treatment of pernicious anemia. No condition which comes to the care of the physician requires a greater display of knowledge and the application of a greater amount of skill, with the possible exceptions of diabetes and arthritis, than does pernicious anemia. Dr. Heck has taken exception to my emphasis on the use of a particular parenteral liver extract for the control of pernicious anemia. If treatment is to be carried out under controlled experimental conditions, I order to evaluate the relative efficiency of various extracts, I should agree with him. But for the practical control of the disease by the general practitioner only those extracts of known anti-pernicious anemia potency should be used in any case, and

this single extract which has the greatest amount of potency will produce the best result with the least inconvenience and expense. An effort should be made to maintain the erythrocyte count at a normal level at all times.

DR W M FOWLER Iowa City With regard to vitamin K, it has been my privilege to follow closely the work of Drs Smith, Brinkhouse and Warner at the University of Iowa on this subject. They developed a method of titrating the prothrombin content of the blood and found that when it gets below 50 per cent of their accepted normal the patient is a potential bleeder. To such patients we have been administering vitamin K, extracted from alfalfa, with excellent results, particularly in cases of hepatic disease and of jaundice. It is a great advance in the control of pathologic hemorrhage in these particular conditions. With regard to the questions brought up about our paper, Dr Harden and I have previously discussed the matter of gastric irritation following the administration of iron. We have found gastrointestinal irritation in some persons with all the forms of iron that we have used. I realize that the question of copper and liver or liver extract in addition to iron is controversial. I can only say that in our experience in patients with hypochromic anemia characterized by iron deficiency we have not found the administration of copper or liver extract necessary. We have been able to control this type of anemia without the administration of these other substances.

## MODE OF ACTION, CLINICAL USE AND TOXIC MANIFESTATIONS OF SULFANILAMIDE

### FURTHER OBSERVATIONS

PERRIN H LONG, MD

ELEANOR A BLISS, ScD

AND

W HARRY FEINSTONE, BS

BALTIMORE

In this communication we will report further observations on the mode of action of sulfanilamide in the treatment of experimental infections and will discuss methods of therapy with sulfanilamide and the toxic manifestations which sometimes arise during the course of sulfanilamide therapy.

### THE MODE OF ACTION OF SULFANILAMIDE

A year ago we<sup>1</sup> reported that "experimental evidence shows that bacteriostasis is the only demonstrable factor in the process which leads to the control of *Clostridium welchii* infection in mice treated with sulfanilamide" and that "observations made by us in experimental streptococcal infections in mice treated with sulfanilamide also could be interpreted as evidence that bacteriostasis plays a role in the control of this type of infection."

In our preliminary report<sup>2</sup> we noted that sulfanilamide in a concentration of 1:10,000 exerted a definite bacteriostatic effect in broth cultures inoculated with small numbers of beta hemolytic and alpha and gamma streptococci, pneumococci of types I and II,

several varieties of neisseriae, *Micrococcus tetragenus*, *Haemophilus influenzae* and *Haemophilus haemolyticus*. The growth of staphylococci, *Eberthella typhi*, *Bacterium paratyphosum* A, *Bacterium paratyphosum* B, *Bacterium enteritidis*, Flexner's bacillus, Shiga's bacillus and several other gram-negative bacilli was not affected by this concentration of the chemical.

During the past year we<sup>3</sup> have observed that increased concentrations of sulfanilamide in broth cultures killed small inoculums of micro-organisms which were merely slowed in their rate of multiplication in a 1:10,000 concentration of the drug. In the course of these investigations it was noted that with the same concentrations of sulfanilamide markedly different effects could be obtained by varying the culture medium. Thus, one medium would enhance the action of sulfanilamide on a susceptible bacterium, while another would inhibit the action of the drug.<sup>4</sup> We have observed that high concentrations of sulfanilamide will exert either a bacteriostatic or a bactericidal effect in broth cultures seeded with small inoculums of streptococci, staphylococci, *Escherichia coli* communis, *Escherichia communior*, *Shigella dispar*, *Bacillus pyocyaneus*, *Bacillus proteus*, *Bacillus aerogenes*, pneumococci, *Eberthella typhi* paratyphoid bacilli and certain other micro-organisms. These observations lead us to believe that in vitro sulfanilamide may affect a wide range of micro-organisms, and it is likely that its mode of action in vitro is the same regardless of the type of bacterium under investigation.

Osgood<sup>5</sup> advanced the hypothesis that "the major action of sulfanilamide on the beta hemolytic streptococcus seems to be a neutralization of the toxins." However, Neter,<sup>6</sup> Gross and his co-workers,<sup>7</sup> Huntington<sup>8</sup> and Kemp<sup>9</sup> subsequently showed that sulfanilamide is essentially without action on the hemolysin, fibrinolysin and erythrogenic toxins of the hemolytic streptococcus. We have observed that high concentrations of sulfanilamide in the blood do not alter positive reactions to the Dick test in human beings. Osgood also stated that sulfanilamide "appears to inactivate a certain fraction of freshly prepared *Perfringens* hemotoxin in vitro." Our experience has been that in guinea pigs and mice inoculated with lethal doses of botulinus toxin death is hastened by treatment with sulfanilamide. Recently Osgood and Brownlee<sup>10</sup> modified their original view as to the mode of action of sulfanilamide, and they now state that "the major action of sulfanilamide is on toxins or aggressins which are responsible for the virulence of the organism and which render it relatively immune to the bactericidal substances present in normal human serum and in monkey serum, but not present in the serum of the mouse." They cite as an example of this type of action the fact that in their experience "sulfanilamide alone has only a slight bacteriostatic effect on pneumococcal infections in marrow cultures or broth cultures, but sulfanilamide plus type specific antipneumococcus serum is far more effective than either alone." Our experience shows that sulfanilamide has a definite bacteriostatic effect in beef infu-

From the biologic division of the Johns Hopkins University School of Medicine.

These investigations have been supported by the Chemical Foundation Inc. of New York City.

Read before the Section on Pediatrics at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

The sulfanilamide used in the experimental procedures was supplied by Abbott Laboratories and the Winthrop Chemical Company, Inc. The 4,4'-diamino diphenyl sulfone was prepared by Dr. George Raiziss of the Dermatological Research Laboratories. The antipneumococcus rabbit serum was prepared by Lederle Laboratories, Inc.

sion broth cultures inoculated with small inoculums of type I pneumococci and that the addition to such cultures of ten units of type I antipneumococcus serum does not enhance the bacteriostatic action of sulfanilamide. These in vitro and in vivo experimental results do not substantiate Osgood's hypothesis.

Since our previous observations<sup>1</sup> on the action of sulfanilamide on certain experimental infections, we have been studying the effect of the drug on pneumococcal peritonitis in mice. We had previously observed<sup>11</sup> that sulfanilamide did not cure mice of experimental pneumococcal infections which had been initiated by the intraperitoneal injection of 100 minimal lethal doses of highly virulent type I, II or III pneumococci. However, we were able to cure about 20 per cent of mice similarly infected if 4-4' diamino diphenyl sulfone was used instead of sulfanilamide as the chemotherapeutic agent.<sup>12</sup>

In the present instance the effects of therapeutic doses of sulfanilamide and 4-4' diamino diphenyl sulfone on

Our purpose in using the heavy inoculums was to enable us to see and count pneumococci in the peritoneal exudates examined immediately after infection had taken place. At this time from one to thirty pneumococcal units (a unit being 1 coccus, pair or chain) were noted to ten oil immersion microscopic fields in the specimens of peritoneal exudate, stained with Way's stain. Repeated experiments with the three types of pneumococci showed definitely that the multiplication of the pneumococci in the peritoneal exudates is slow in mice treated with sulfanilamide or the sulfone compound than in the controls and that both of these compounds seem to be acting as purely bacteriostatic agents in changing the normal course of the infection.

It is noteworthy that the observed bacteriostasis (which is more marked in the mice treated with the sulfone compound) is unaccompanied by any especial degree of phagocytosis. In this report the observation differs from that made on the peritoneal exudates from mice infected similarly with hemolytic streptococci or

† % P = percentage of phagocytes (polymorphonuclear leukocytes and monocytes) containing ingested pneumococci  
‡ Mouse inoculated with 200 units of type I concentrated antipneumococcus rabbit serum seven hours after infection

the peritoneal exudates of mice with experimental type I, II and III pneumococcal infections were investigated. The procedure followed in such a study is given in detail elsewhere.<sup>1</sup> Therapy was commenced one-half hour before the intraperitoneal injection of the infecting organisms and was continued at four hour intervals until three or four doses of the compounds had been given. Twelve mice were used in each experiment, one third serving as controls and another third being treated with sulfanilamide, while the remainder were treated with the sulfone compound. Immediately after infection, examinations of the peritoneal exudates were made, and these were repeated thereafter at suitable intervals. Heavy inoculums (from 700,000 to 3,500,000 organisms) of highly virulent type I, II or III pneumococci from twelve hour dextrose and blood broth cultures of mouse passage strains were used in each experiment.

*Clostridium welchii*. That the process was not the result of leukocytic damage by the infection or the therapy is shown in table 1.

In this experiment the mice were infected with type I pneumococci. Definite bacteriostasis could be noted in the treated group. After the infection was well established (at the seventh hour), two mice in each group received 200 units of type I antipneumococcus rabbit serum by the intraperitoneal route. This treatment with type-specific serum resulted in an immediate wave of phagocytosis in both the controls and the treated mice, thus showing clearly that the leukocytes were capable of phagocytizing the pneumococci if conditions were favorable. This type of experiment was repeated several times with both type I and type II antiserum with like results. If normal rabbit serum was substituted for the type-specific antipneumococcus serum no appreciable increase in phagocytosis was noted.

While no changes could be observed in the capsular structure of the pneumococci seen in stained exudates from the mice treated with sulfanilamide or the sulfone compound, certain definite alterations in the organisms

11 Long P H and Bliss Eleanor A South M J 30 479 (May) 1937  
12 Lemstone W H Bliss Eleanor A Ott E and Long P H Bull Johns Hopkins Hosp to be published

were observed when they were compared with the pneumococci seen in the exudates from the untreated control mice. During the first ten to twelve hours after inoculation, the pneumococci from the exudates of the treated mice tended to chain formation, while those in

Chart 1—Deaths from experimental streptococcal infections in mice treated parenterally with varying amounts of sulfanilamide

the exudates of the controls multiplied rapidly as diplococci. Also in the exudates of the treated mice, while the capsular material appeared intact, a somatic element would occasionally be missing from the pneumococcus chain or such an element would be noticeably smaller than that of its adjacent cocci. However, after the twelfth hour such alterations in structure were not commonly observed. These variations from the normal would seem to be indicative of an alteration in the reproductive mechanism of the pneumococci. The experimental infections proceeded to their usual fatal termination in essentially the same manner in the treated and in the control mice. However, in the treated mice, death, instead of taking place from twelve to twenty hours after inoculation, as in the controls, was delayed to from twenty-four to forty-eight hours. This prolongation of life was directly correlated with the slower reproduction of the pneumococci in the peritoneal exudate. Therefore we consider these observations as strongly supporting our theory that sulfanilamide (and the sulfone compound) acts by inhibiting the multiplication of organisms in the tissues of the infected host.

#### THE USE OF SULFANILAMIDE IN THE TREATMENT OF BACTERIAL INFECTIONS

There is ample clinical evidence as to the value of sulfanilamide therapy in the case of hemolytic streptococcus infections in human beings.<sup>13</sup> Sulfanilamide also appears to have a definite place in the treatment of meningococci,<sup>14</sup> gonococci<sup>15</sup> and *Bacillus welchii*.<sup>16</sup>

infections, melitensis<sup>17</sup> and certain infections of the urinary tract.<sup>18</sup> Our experience leads us to believe that sulfanilamide is not highly effective in the treatment of pneumococcal lobar pneumonia, although it may be of some value in the treatment of other types of pneumococcal infections.<sup>19</sup>

While a considerable clinical experience will be needed before accurate standards of dosage for sulfanilamide can be established, certain experimental observations have a bearing on this question.

In chart 1 is shown the effect of varying amounts of sulfanilamide on the survival rate of mice experimentally infected with beta hemolytic streptococci. It is to be noted that the larger the dose of the drug the greater was the survival rate of the mice and that the average duration of life was longer for the more heavily treated mice.

In chart 2 may be seen the effects of a single daily dose of 10 mg of sulfanilamide, as contrasted with three divided doses of 3.3 mg a day, on the course of experimental hemolytic streptococcus infections in mice. The survival rate and the average duration of life were definitely better for mice treated with divided doses for three days than for mice receiving a single dose a day for three days, although in all instances the total dose was the same.

These experimental observations, showing increased survival rates with the larger doses and the importance of spaced doses as opposed to single doses of sulfanilamide, when coupled with our clinical observations made

Chart 2—The effect of single daily doses and of divided daily doses of sulfanilamide the total amount of the drug being the same, on experimental streptococcal infections in mice

on 408 patients who were treated with sulfanilamide, lead us to believe that certain tentative standards of sulfanilamide therapy can be established for human beings.

408 patients to sulfanilamide therapy and on a study of the levels of the drug in the blood as measured by Marshall's method<sup>20</sup> in 126 of these patients.

With severe infections it is important to attain an effective level in the blood as soon as possible. We therefore advise that a large initial dose of sulfanilamide be given in order to bring about the desired level of 10 mg per hundred cubic centimeters as quickly as possible and that this level be maintained and increased by doses of the drug given at four hour intervals both day and night. The maintenance dose should be given until a marked clinical improvement in the condition of the patient is noted. It should then be decreased slowly day by day, but the administration should not be entirely discontinued until the patient is ready to be up and about. If this routine is followed, recurrences of infection will be rare. It is important to remember that the administration of sulfanilamide should be discontinued only under the most exceptional circumstances when there is a severe infection.

In the case of milder tissue infections, amenable to sulfanilamide therapy, levels of sulfanilamide in the blood of from 5 to 10 mg per hundred cubic centimeters are generally adequate to bring the infection under control. Here again it is important to maintain an even concentration of the drug in the tissues, and because of this a four hour schedule of doses is best if circumstances permit its use.

If the patient cannot swallow tablets, if vomiting is present or if there is any reason to believe that the absorption of sulfanilamide from the gastrointestinal tract might be faulty, the drug can be given by hypodermoclysis. In the preparation of sulfanilamide for parenteral use, a one-sixth molar solution of sodium lactate (18.67 Gm of sodium lactate per liter) and Hartmann's solution are the best solvents, although physiologic solution of sodium chloride can be used. It is best to use a 1 per cent solution of sulfanilamide, and this may be sterilized by boiling for three minutes.

The calculated daily dose is the same as that for the first day of the oral dose. The initial hypodermoclysis should contain one half of the calculated first day dose of sulfanilamide. Subsequent hypodermoclyses should be given at eight hour intervals and should contain one third of the calculated first day dose of sulfanilamide. The parenteral use of sulfanilamide is, however, a less satisfactory method of administering the drug, and in every instance as soon as the patient is able to take sulfanilamide by mouth at regular intervals its parenteral use should be discontinued.

There is no unanimity of opinion as to what constitutes the most satisfactory method of treating gonococcal infections with sulfanilamide. However, one thing seems certain, and that is that this type of therapy is always more successful and the chance of cure greater<sup>21</sup> if the patient is hospitalized. The report of Mahony<sup>21</sup> points to the fact that large doses (12 Gm. every four hours) of sulfanilamide given for eight days to hospitalized patients bring about excellent results in the treatment of both acute and chronic gonococcal urethritis. The results obtained in the treatment of gonorrhea in the female by J. Herman Long indicate that a longer period of sulfanilamide therapy is needed for females than for males. He advises intensive treatment for a week followed by decreasing doses of sulfanilamide for three weeks. The complications of acute or chronic gonorrhea should be treated in the same manner as are the original manifestations of the disease.

For patients with gonococcal infections who have been treated with sulfanilamide the criteria of cure are not as yet well established. Our experience leads us to suggest that the minimal criteria of cure should be repeatedly negative results of clinical and laboratory examinations (cultures and smears) for at least six months after the cessation of therapy. If these requirements are adhered to as a routine, few symptomless carriers will be turned loose to infect the public.

TABLE 3—The Amounts of Sulfanilamide Necessary to Establish Therapeutically Effective Blood Levels (from 5 to 10 Mg per Hundred Cubic Centimeters) in Patients Ill with Mild or Moderately Severe Infections for Which Sulfanilamide Therapy Is Indicated

The successful treatment with sulfanilamide of infections of the urinary tract depends to a large degree on the obtaining and maintaining of a satisfactory concentration of sulfanilamide (nonacetylated) in the urine.<sup>22c</sup> Such a concentration cannot be obtained in patients who have moderate or marked impairment of

21 Mahony J F Communication to the American Neisserian Society May 16, 1936  
22 Long J H Personal communication to the authors

the renal function. Patients with impaired renal function must always be observed carefully while receiving sulfanilamide lest the drug accumulate in their tissues. We have noted that the following concentrations of sulfanilamide are generally effective in the control of infections of the urinary tract: for *Staphylococcus albus* infections from 50 to 100 mg per hundred cubic centimeters, for *Staphylococcus aureus* infections from 100 to 150 mg, for *Escherichia coli* infections from 200 to 250 mg, for *B. aerogenes* infections from 250 to 300 mg, for group B beta hemolytic streptococcus infections from 250 to 300 mg and for *Proctus* infections from 300 to 400 mg. Enterococcal infections of the urinary tract are unaffected by sulfanilamide therapy.<sup>23</sup>

Tables 2 and 3 show that the amount of sulfanilamide per pound or kilogram of body weight required to establish adequate levels of the drug in the blood is considerably greater for children than for adults. This variation is due to the fact that the fluid intake per kilogram of body weight is normally greater with children than with adults, and when fever is present this difference is even more marked. Sulfanilamide is excreted almost entirely in the urine.<sup>21</sup> Thus, the greater the volume of urine, the greater the excretion of sulfanilamide. This brings us to the question of how much fluid should be given to a patient who is receiving sulfanilamide. Our experience definitely shows that if large amounts of fluids are given, it is difficult to obtain and maintain effective levels of sulfanilamide because the drug is rapidly excreted. Because of this we do not force fluids too strenuously on a patient who is receiving sulfanilamide.

The question as to whether sulfanilamide should be given by the intrathecal route in cases of meningococcal, streptococcal or pneumococcal meningitis is not as yet settled. We do know that sulfanilamide easily passes over into the spinal fluid in about the same concentration as exists in the blood. Because of this we feel that intrathecal therapy with the drug is not necessarily indicated for meningeal infections. Sulfanilamide can be found in about the same concentration as exists in the blood in transudates and exudates in all the body cavities. It also penetrates into the pus in closed abscesses and is present in purulent discharges. In the treatment of purulent infections we have noted that recurrences are frequent if the administration of sulfanilamide is discontinued before a complete clinical cure has been effected. Thus, in cases of draining abscesses, of streptococcal osteomyelitis and of middle ear or mastoid infections the drug should be given for at least ten days after the patient is completely well.

While it seems best not to administer saline cathartics during the course of sulfanilamide therapy, no other drugs seem to be contraindicated. Acetylsalicylic acid, the barbiturates, digitalis, arsphenamine, ferrous sulfate and many other drugs may be used in conjunction with sulfanilamide if they are indicated. Sodium bicarbonate should always be administered when sulfanilamide is being given in order to prevent clinical acidosis from developing. The antidote for sulfanilamide is water, of which large quantities should be administered to the patient if it is desirable to free him of sulfanilamide rapidly.

#### THE TOXIC MANIFESTATIONS OF SULFANILAMIDE

In table 4 are recorded the incidence and types of toxic manifestations noted in the first 408 patients who were treated with sulfanilamide in the Johns Hopkins Hospital.

In our original report<sup>2</sup> we noted the occurrence of certain cerebral toxic effects in mice and human beings. Among the most common ones noted in human beings are anorexia, nausea, vomiting, dizziness and headache. Rarely have these manifestations been severe enough in ward patients to warrant discontinuing administration of the drug. In ambulatory patients these symptoms may constitute a serious problem. Alcohol is contraindicated during sulfanilamide therapy as it tends to accentuate the cerebral toxic manifestations. Patients who are receiving sulfanilamide should be warned against driving automobiles, because the dizziness and

Type of Infections, adult group	Type of Infections, children		
Streptococcal infections	Streptococcal infections	107	43
Other infections	Other infections	200	
Toxic Manifestation	Frequency, Adults	Frequency, Children	Comment
Dizziness, anorexia, nausea, vomiting	Anorexia common	Anorexia common	Rarely severe enough to warrant discontinuing use of sulfanilamide
Cyanosis	90 to 100%	90 to 100%	Of little clinical importance
Simple fever	9%	3%	Very important warning sign, always stop use of sulfanilamide
Dermatitis	1.6%	3%	Best to stop use of sulfanilamide
Acidosis	3.6%	2%	Can be prevented if sodium bicarbonate is given as a routine
Renal irritation	0%	0%	If renal function is low sulfanilamide is not excreted well
Jaundice (without anemia)	0.6%	0%	Stop use of sulfanilamide
Mild hemolytic anemia	Common	Common	Not dangerous, continue use of drug and observe patient carefully
Acute hemolytic anemia	2.9%	8.9%	In general stop use of sulfanilamide; drug may be given with multiple transfusions
Agranulocytic angina	0.3%	0%	Stop use of sulfanilamide

\* These 408 patients were kept in bed and under close observation during the major portion of their treatment with sulfanilamide.

decreased mental acuity sometimes seen may render them dangerous on the road.

The mechanism of the cyanosis noted in the course of sulfanilamide therapy is as yet unclear. Marshall and Walz<sup>25</sup> expressed the opinion that the formation of methemoglobin is always responsible for the cyanosis, while Wendell<sup>26</sup> stated that varying degrees of methemoglobinemia were found in 200 patients treated with sulfanilamide. Neither of these observers has noted sulfhemoglobin in the blood of cyanotic patients.

Simple fever unaccompanied by other toxic manifestations occurred frequently in our patients. Often one is asked how to differentiate the fever due to the drug from fever due to the infection. It is interesting to note in this respect that in only two of the patients in this series in whom fever developed as a toxic mani-

<sup>26</sup> Wendell W B Personal communication to the authors April 1 1938

festation of sulfanilamide therapy was this question difficult to answer. All the other patients had one or more days of normal temperature before the drug fever developed.

The days of the occurrence of fever or dermatitis are shown in table 5.

In addition to simple fever due to sulfanilamide we have noted that almost all patients in whom dermatitis, acidosis, acute hemolytic anemia or agranulocytic angina developed also showed an early febrile response. This leads us to believe that the appearance of fever constitutes an important warning sign in the control of patients being treated with sulfanilamide and that administration of the drug should be promptly discontinued when an unexplained fever develops.

As simple fever is a fairly common toxic manifestation in the course of sulfanilamide therapy, the question of whether one may resume treatment with the drug after the fever has disappeared is of importance. Our observations show that it is impossible to predict whether a patient will have another febrile reaction if sulfanilamide therapy is resumed. However, because of the sharpness and intensity of the febrile reactions noted in certain patients after the resumption of sulfanilamide therapy, we believe it wise to administer a small test dose (0.3 Gm. or 5 grains) to patients who

Dermatitis number of patients					2		"			2					1

have previously had a febrile response. If a sharp febrile response is noted within twelve hours it is unwise to continue giving the drug.

The dermatitis due to sulfanilamide is generally a maculopapular, "measly" eruption which may or may not be accompanied by fever or by a history of exposure to light. In some instances, however, we have noted multiform and urticarial lesions, scarlatiniform eruptions and purpuric rashes. It is generally wise to discontinue giving sulfanilamide if a rash occurs. Again, it is impossible to predict in the individual case whether or not an eruption will occur if sulfanilamide is administered a second time.

The routine administration of sodium bicarbonate with sulfanilamide will prevent the occurrence of clinical acidosis, which appears to be due to a loss of sodium and potassium in the urine.<sup>11</sup> We have not noted any evidence of renal damage or irritation which could be attributed to sulfanilamide. Simple jaundice (without anemia) occurred in two of our patients. With both, withdrawal of the drug resulted in a rapid clearing of the jaundice.

Anemia of the hemolytic type occurred frequently in this series of patients. Fortunately, in most of them it was mild and slow in developing. A drop in the hemoglobin content of from 10 to 20 per cent is common in the course of sulfanilamide therapy, especially if the treatment is prolonged for ten days or more. This slowly developing anemia is not accompanied by bilirubinemia, although increases in the reticulocyte count above normal limits are the rule after the hemo-

globin content begins to drop. Urobilin is almost constantly present in the urine. Our observations lead us to believe that this slowly developing, mild anemia is not a contraindication to the continuation of sulfanilamide therapy.

Acute hemolytic anemia<sup>27</sup> characterized by a rapid fall in the red blood cell count and the hemoglobin content, moderate to marked leukocytosis, marked reticulocytosis, bilirubinemia, urobilinuria and, in certain instances, porphyrinuria, occurred in 3 per cent of the adult patients and in 8.9 per cent of the children in this series. This type of toxic manifestation is one of the most serious encountered in the course of sulfanilamide therapy. It has generally been severe enough to necessitate one or more transfusions. It occurs within twenty-four to seventy-two hours after treatment is begun. The maximal anemia generally develops within three days after the hemolytic process is initiated. All the patients show a definite rise in temperature during the anemic phase. This toxic manifestation is more common in children than in adults. In three or four cases in which therapy with sulfanilamide was resumed after the hemolytic process had subsided, there was a recurrence of the acute hemolytic anemia.

The mechanism of this type of anemia is not as yet clearly understood, but it would seem to be the result of an idiosyncrasy toward sulfanilamide. There is no evidence that any one type of infection predisposes a patient toward this form of anemia. Experience has shown that, in general, the use of sulfanilamide should be discontinued if acute hemolytic anemia develops. However, if a patient is critically ill with an infection, the sulfanilamide may be given despite the acute hemolytic anemia if multiple transfusions are used to maintain a proper level of red blood cells and hemoglobin in the blood.

Agranulocytosis has been reported in the course of sulfanilamide therapy.<sup>28</sup> We observed one patient suffering from gonococcal arthritis and urethritis in whom this toxic manifestation developed toward the end of the third week of treatment. He showed the typical picture of agranulocytic angina. Treatment designed to rid him of sulfanilamide was immediately instituted, and within ten days he had made a complete recovery from this blood dyscrasia. The mechanism of the production of serious leukopenia and agranulocytosis by sulfanilamide is as yet unknown.

#### SUMMARY AND CONCLUSIONS

Further observations which we have made on the mode of action of sulfanilamide, both in vitro and in vivo, substantiate our earlier observations that the drug decreases the rate of multiplication of susceptible bacteria. We have been unable to confirm certain of Osgood's<sup>6</sup> observations regarding the antitoxic action of sulfanilamide. A study of the effects of treatment with this drug and with 4, 4' diamino diphenyl sulfone on the peritoneal exudates of mice suffering from experimental pneumococcal peritonitis shows that these chemotherapeutic agents may alter slightly the essential structure of the pneumococcus. However, the chief difference between the treated mice and the control mice was that, at any given observation, there were always definitely fewer pneumococci in the exudates from the

treated animals than in those from the controls. Because of the absence of any appreciable degree of phagocytosis in the exudates from any of the groups of mice, we interpret this observation as meaning that the chemotherapeutic agents retarded the multiplication of the pneumococci in the treated mice. These observations complement our previous view<sup>1</sup> that sulfanilamide has a bacteriostatic action in the control of experimental *B. welchii* infections in mice.

The proper clinical use of sulfanilamide must, in our opinion, be based on a knowledge of the factors concerned in its absorption and distribution in the body. We believe that levels of sulfanilamide of from 10 to 15 mg per hundred cubic centimeters of blood are favorable for the control of severe infections. Lower levels (from 5 to 10 mg) are satisfactory for the control of mild or moderately severe infections. The maintenance of an even level is dependent on dosage over the entire twenty-four hour period. Administration of the drug should not be discontinued (unless severe toxic manifestations appear) until a clinical cure of the infection has been effected. Because of the possible toxic manifestations of the drug, patients receiving sulfanilamide should, whenever possible, be hospitalized.

This chemotherapeutic agent has many toxic effects, and because of them the patient should be carefully supervised while sulfanilamide is being administered. This supervision should consist of careful clinical observations, frequent and regular temperature recordings, a daily hemoglobin determination and a daily total white blood cell count. If these procedures are adhered to as a routine, the toxic manifestations of sulfanilamide will be noted in their inception. In conclusion, we cannot stress too strongly the fact that the patient who is receiving sulfanilamide needs the intelligent and careful supervision of a physician.

#### ABSTRACT OF DISCUSSION

DR FRANCIS SCOTT SMYTH, San Francisco. From a rather limited clinical acquaintance the conclusion has been reached that the dose of sulfanilamide may vary with the organism, the strain of the organism, the severity of the infection and the resistance of the patient. I should like to mention the treatment of meningococcic meningitis. I have questioned for some time whether the intrathecal administration is entirely scientific if the drugs or antisera are expected to reach the deeper sulci, where some of the pathogenic process is located. So with sulfanilamide, the drug is rapidly diffusible and should be administered by mouth, lumbar puncture being used only for drainage. The result has been entirely satisfactory to me. In contrast with Dr Schwentker's report that the level in the spinal fluid could not be raised high enough, I might say that the level in the spinal fluid was 22 mg per hundred cubic centimeters and the level in the blood 24, the titers being taken simultaneously. The authors mentioned the necessity of watching the kidney, which is important. I think perhaps practitioners who deal with children are inclined to stop the medication too early, particularly in otitis media and mastoid infections. I think we have pushed fluids because of a certain fear and again because the metabolism of the child would require a greater fluid intake. The authors did not mention methylene blue. The reports of Hartmann and Wendell strongly suggest that cyanosis deserves some consideration in the presence of pulmonary infection or of anemia. I have used it in a limited way. However, without going into the controversy about methemoglobinemia or the action of methylene blue, I believe that physicians should keep an open mind about the use of the substance, particularly before operation or for severely anemic patients.

DR THOMAS B COOLEY, Detroit. I have made no such careful study as the authors have and have only the experience of a large, rather undermanned clinic in which we cannot do

all the things we should like to. Our results in meningococcic infections have been so good that we have adopted sulfanilamide as our standard medication, using at present no serum at all. We are not having any epidemic, however, and there are only sporadic cases. The service in our hospital which has had the most striking results with sulfanilamide has been the otolaryngologic in the streptococcic complications of otitis media—mastoiditis, septicemia and meningitis. The effects here have been remarkable. I think that no one has been impressed with the desirability of using sulfanilamide as a routine in the treatment of the more transient disorders of the pharynx and nasopharynx, which ordinarily will not last more than three or four days. I should like to be able to discuss the dangers of the drug. We have seen almost none of them. The authors' figure of 10 per cent for hemolytic anemia surprised me. We have had no such results. This may be because we have not used such large doses. We seldom run our blood levels to 15 mg per hundred cubic centimeters. In most cases, with good results, the levels have been 10 mg or less per hundred cubic centimeters. We have had three patients with granulopenia. One came in with thrombopenia, and granulopenia developed within eighteen hours after the first dose of sulfanilamide. I do not suppose this to have been due to the drug. Another had transient leukopenia almost immediately after the beginning of administration. One patient, who had gone through prolonged septicemia, died finally in a state of agranulocytosis much like the aplastic anemia occasionally developing in the course of sepsis, and the marrow was of the same type. He had been intensively treated with sulfanilamide for a month but I am not inclined to believe that the drug was responsible for the blood picture. I have one small contribution to make regarding gonorrheal ophthalmia. In a series of thirty control cases and fifteen cases in which sulfanilamide was used the average stay in the hospital in control cases was 30.14 days and for those in which sulfanilamide was used 5.8 days. The younger the child, the larger the dose necessary to obtain a particular level. The two patients with very low levels had determinations in the early morning after a night without the drug, which was the practice in this series. It may be noticed too that the good results were obtained with generally low sulfanilamide levels, averaging a little under 5 mg per hundred cubic centimeters for the series.

DR PERRIN H LONG, Baltimore. There were a lot of things we didn't speak about this morning because of lack of time. We tried to stick as close as possible to the clinical side of the use of sulfanilamide. That there may be no misunderstanding, I shall state that my associates and I feel that the large doses of sulfanilamide are needed only in severe infections in which there is danger of death. To bring mild infections under control such large doses of the drug are not needed. I do not believe now that the intrathecal use of sulfanilamide is necessary in meningococcic meningitis. I think the patients can be treated by mouth if one is sure that the drug is being absorbed, and the only way to know this is by determining the level of sulfanilamide in the blood. We have used methylene blue in the control of cyanosis, but by and large in our experience cyanosis has never constituted a problem in the general therapy of the patient. We neglected to mention that in severe infections, in order to get the level in the blood up rapidly, we limit the intake of fluids to 3,000 cc a day in adults, and since we have been limiting fluids we have had much better results. With regard to Dr Cooley's suggestion that our frequency of hemolytic anemia was due to the large doses, I have recently been over all of the cases to date. We have had about twenty-eight or thirty cases in the hospital, and, strangely enough, there is little evidence that the amount of the drug had anything to do with the development of acute anemia, in the sense that high doses and low doses produced it about equally. An interesting thing is that four patients who had acute hemolytic anemia were given sulfanilamide again in the Johns Hopkins Hospital at a period of from two months to a year afterward. In three of the four patients the anemia developed on exactly the same day as in their previous course of sulfanilamide. The fourth patient for some unknown reason did not become anemic. Hence we think the anemia is more a manifestation of idiosyncrasy than of a direct effect of acute toxicity of the drug.

# THE PROBLEM OF DISRUPTION OF ABDOMINAL WOUNDS AND POST-OPERATIVE HERNIA

A REVIEW OF 9 000 CONSECUTIVE ABDOMINAL INCISIONS

ALBERT O SINGLETON, M.D.  
AND  
TRUMAN G BLOCKER JR. M.D.  
GALVESTON, TEXAS

Occasional contributions have appeared on the subject of disruption of wounds for a long time, but more than forty articles have been found in the American literature alone during the last few years as evidence of its importance. Because of these articles, or for other reasons, there has been a recent renewed interest in the subject, and we can say undeniably that disruption and postoperative hernia are on the decrease. Since postoperative hernia is so intimately associated with disruption, one cannot be satisfactorily discussed without the other.

Jenkins<sup>1</sup> has reviewed the recent literature on wound disruption, bringing the reported cases up to date, and has added thirty-six cases from the University of Chicago surgical clinic to increase the number reported to 1,294. To these cases we have added forty-nine cases reported by Fallis<sup>2</sup> and twenty-two by Glenn and Moore,<sup>3</sup> with sixty-one of our own. A study of the data on these cases from many clinics reveals striking uniformity in the frequency of disruption (from 0.6 to 3 per cent) as well as in mortality (from 25 to 40 per cent). The etiologic factors are also similar, while the suggestions for remedying the condition are numerous.

In the study of this problem we have reviewed 9,000 consecutive abdominal incisions made in the surgical and gynecologic services of the John Sealy Hospital. Sixty-one disruptions and 160 postoperative hernias were recorded.

It is important to remark that our follow-up records of postoperative hernias are incomplete, and unquestionably a number have not been recorded. A somewhat higher percentage of hernias would therefore be nearer correct.

Almost two thirds of the patients operated on were females, thus accounting for the higher percentage of disruption in that sex. Approximately 65 per cent of the patients were between the ages of 25 and 50 years, but since this is the time during which most patients are subjected to surgical operations, age is not significant. Negroes showed relatively the same number of disruptions, but hernia occurred in a greater number.

Drainage of the peritoneal cavity through an abdominal incision predisposes to both disruption and hernia. This brings up the question of infection which made the drainage necessary. It is readily seen that in the cases in which drainage was done infected wounds more often developed. At this time we should like to

call attention to the importance of protecting the wound from soiling in operations in the presence of abdominal infection. It is possible to keep a wound clean and to secure primary healing in a large percentage of cases even though pus is encountered during the operative procedure.

Table 3 shows that thirty-nine of our postoperative hernias were in cases in which drainage was not done. These might probably be considered disruptions, since some degree of separation of the wound must have occurred during the postoperative period.

The most common causes of disruption and hernia are (1) infection and hematoma, (2) delayed wound healing, (3) faults of the suture material, including allergic reactions thereto and hypoproteinemia, and (4) coughing, vomiting and gaseous distention.

## INFECTION AND HEMATOMA

Infection was a contributing factor in disruption in 22 per cent of the 1,294 cases reviewed by Jenkins. In our series infection occurred in 60 per cent (table 4). It is common knowledge that low grade infection may be present without suppuration. Disintegration of

absorbable suture material is greatly hastened by infection. Howes and Harvey<sup>4</sup> demonstrated that within three to six days catgut of any size or preparation lost its tensile strength in the presence of infection. If silk or linen is used, the tissues readily cut through because of the softening and disintegration of the tissues sutured in the presence of infection. Hematoma is a generally recognized cause, not only by preventing union but by predisposing to infection.

## DELAYED WOUND HEALING

It is common knowledge that wound healing is delayed in patients showing emaciation, general debility or old age, and this is especially noticeable in patients with cancer. Records reveal that 25 per cent of disruptions occur in cases of malignant growth. As seen in table 4, 22.9 per cent of our cases can be classed as instances of delayed healing or nonunion.

From the Department of Surgery, University of Texas School of Medicine and the John Sealy Hospital.

FAULTS OF THE SUTURE MATERIAL

As pointed out by Howes and Harvey,<sup>1</sup> local exudative wound reactions causing edema result in softening not only of catgut but of the tissues which are being held by the suture

The holding power of a stitch is in direct proportion to the degree of condensation of connective tissues in the structure in which the stitch is placed. The holding power of the stitch decreases rapidly and more rapidly than does the strength of catgut

Fig 1—Modified Sloan incision showing the rectus muscles retracted laterally and the posterior rectus sheath and linea alba cut transversely in the direction of their fibers. UMB indicates umbilicus. (South Surgeon 3:235 [Sept.] 1934)

The controversy over catgut versus silk, linen or silver wire goes on without a decision. Although evidence continues to accumulate against catgut, it remains the suture material preferred by the greater number of surgeons. The desire for a material that would be

If we assume that their statement is true, the problem of selecting suture material becomes less difficult. Suture material only slightly stronger than the tissues sutured is preferable. Large or overstrong sutures strangle the tissues. Therefore, the approximation of nontraumatized noninfected tissues under tension without strangulation and with a minimum amount of suture material favors good union.

Rhoads, Hottenstein and Hudson<sup>5</sup> studied the decline in the strength of catgut after exposure to living tissue and concluded that "tanned, iodized catgut possesses more resistance to the action of tissue fluids than medium-hard chromic catgut. Also, it is much less affected by infection than medium-hard chromic or plain catgut."

Allergic Reactions—Sensitivity or allergic reaction to catgut as an argument against the use of this material for sutures has been seriously presented by several

absorbed resulted in the use of catgut by Physick as early as 1816. Lister in 1868 devised methods of sterilizing catgut, and further perfection of methods of sterilization has removed its most objectionable features. Jenkins<sup>4</sup> after clinical tests of the duration of tensile strength of catgut, concluded that "plain catgut lasts 5-6 days by tension-suture tests but that it becomes untied in the tissues in 2-3 days."

There is a definite place in the practice of surgery for absorbable suture material which can be depended on to maintain its tensile strength for at least ten to fifteen days.

duced into such an animal a marked local reaction usually occurs at the site of its introduction. This frequently results in a rapid absorption of the catgut and often disruption of the

healing of wounds and expressed the belief that the failure of wounds to heal is associated with the hypoproteinemic state, a condition which is present in many patients subjected to operation on the gastric, duodenal and biliary tracts They also found that in animals lyophile plasma is efficacious in the correction of hypoproteinemia and in that way prevents disruption of wounds

The controversy over suture material continues and, so far as we can see, unnecessarily From information available from the literature, substantiated by personal experience, we can say that suture material in excess

of the minimum in size and amount is not conducive to good wound healing The reaction of the tissue to excessive suture material is deleterious, and strangulation of tissue by excessive tension is the surest way to prevent healing The strength of the suture material need not be greater than the strength of the tissues sutured because the tissues (fascia) will cut through irrespective of the material used for sutures if tension is greater than the tissue will bear Reports show that, irrespective of the type of suture material used, disruptions may occur Catgut, plain, iodized or chromic, has been used in the cases we report, except in a few instances in which silk linen or silver wire was used Bearing in mind the foregoing information, we have for some time used No. 0 single or double chromic catgut for closing abdominal wounds, except with the McBurney incision where No. 1 plain catgut is used We are conscious of the revival of interest in the use of silk suture

COUGHING VOMITING AND GASEOUS DISTENTION

Coughing vomiting and gaseous distention are factors that cannot be disregarded as contributing to the occurrence of disruption and hernia The first is important since a severe postoperative cough is impossible to anticipate and difficult to control On the other hand, vomiting and gaseous distention can be anticipated and completely obviated by gastric suction We are convinced that gastric suction will absolutely prevent postoperative vomiting and distention if done as a routine efficiently in all cases during and after abdominal operations This has been our practice for the past

three years, the tube being passed before the anesthesia is started The results have been eminently satisfactory

ANATOMIC INCISIONS

Among the many causes of wound disruption and postoperative hernia we wish to call attention to one which is of the greatest importance, although appar

7 Thompson W D Ravdin I S and Frank Irving L Effect of Hypoproteinemia on Wound Disruption Arch Surg 36 500 518 (March) 1938

ently it has received little attention either in the literature or in actual practice. We refer to the use of nonanatomic incisions. We are convinced that generally too little consideration has been given to the anatomic structures of the abdominal wall in making abdominal incisions.

Fig 5—Lateral transverse incision showing closure of the posterior sheath of the rectus muscle, the internal oblique muscle, the transversus muscle and the peritoneum in one layer.

It is true that occasional disruption is possible irrespective of the type of incision used, but, on the other hand, certain commonly used incisions are much more prone to give trouble than others. This is particu-

larly true in the upper part of the abdomen, where the number of faulty wounds is relatively far greater than in the lower part. This is easily accounted for when one considers the anatomy of this region as it relates to the commonly used vertical rectus or midline incision. As a general proposition a surgeon hesitates to cut muscles or tendons across their fibers, but in the upper vertical incision this is done. The strength of the abdominal wall depends largely on muscles and fascia. The muscles terminate in fascia at various places, and this fascia will be found in abundance in those parts of the wall where stress is greatest. This can be seen in the sheaths of the rectus muscle, both

anterior and posterior. These sheaths are the tendinous continuations of the external, internal oblique and transversus muscles. It is also significant that the greatest tension is in a direction parallel with the fibers of the fascia. In the upper part of the abdomen, therefore, the direction of the fibers and the tension is largely in a transverse direction. The posterior rectus sheath is the tendinous continuation of the internal oblique and the transversus muscle, which are respiratory muscles and constantly in action, and during the acts of coughing and vomiting the strain on this fascia is great. It is too much to expect this structure (which is cut across in the usual vertical incision), sutured

together with its fibers end to end, to withstand the postoperative strain which may be thrown on it regardless of the suture material or the way it is used. By splitting this fascia in a transverse direction in line with its fibers, preservation of the strength of the abdominal wall is guaranteed. Various types of transverse incision can be used with this objective in mind. The most satisfactory of these is the incision described

Fig 6—Lateral transverse incision showing closure of the external oblique muscle and the anterior sheath of the rectus muscle.

by Sloan.<sup>8</sup> We have used this incision slightly modified for ten years, with perfect satisfaction to us as well as to the patients. One of us described this incision previously.<sup>9</sup>

8 Sloan G A. New Upper Abdominal Incision. *Surg Gynec & Obst* 45: 678 (Nov.) 1927.  
9 Singleton Albert O. Improvement in Management of Upper Abdominal Operations Stressing Advantages of Anatomical Incision. *South M J* 24: 200-206 (March) 1931. Anatomical Importance of Fascia in Abdominal Wall. *South Surg* 3: 235-243 (Sept.) 1934.

Another type of transverse incision which we have found extremely satisfactory both for the security of the wound and for the easy access to the abnormality sought is a lateral transverse incision. This incision is used on the right side for operations on the biliary passages, and on the left side for operations on the splenic flexure of the colon, and particularly for splenectomy. The incision begins near the midline, from 3 to 4 inches above the umbilicus, extending obliquely downward and outward, just below the costal margin, almost to the iliac crest just posterior to the anterior superior spine. This is in the direction of the fibers of the internal oblique muscle. The anterior sheath of the rectus muscle is cut transversely and the muscle freed from the sheath for a short distance above and below. The incision is continued across the fascia of the external oblique muscle for 2 or 3 inches in line with the cutaneous incision and the external oblique muscle is retracted farther laterally. The rectus muscle is retracted toward the midline, and its posterior sheath is split from the linea alba laterally into the

Fig. 7—Lateral transverse incision showing closure of the cutaneous incision

internal oblique and transversus muscles. The internal oblique muscle is split and the transversus and peritoneum cut in the same incision. This gives an advantageous exposure of the gallbladder, bile ducts, appendix and pyloric end of the stomach on the right side. The wound comes together and is quickly and easily sutured in layers without tension. The wound may be considered unanatomic in that the ninth and tenth intercostal nerves may be injured when cut or retracted out of the way. A numbness results over an area of skin below the incision for a few weeks but soon disappears. For splenectomy this incision has been the source of particular satisfaction. The largest spleens may be removed with excellent exposure, and perfect control of the situation is possible throughout the operation.

#### SUMMARY

Disruption of abdominal wounds and postoperative hernia are on the decrease. This is due primarily to a revival of interest in the subject, resulting in greater

care in making and closing wounds, another important factor is the more successful postoperative care due to the increasing use of gastric suction, obviating vomiting and gaseous distention, which have been serious contributing factors.

Disruption of wounds and postoperative hernia in the upper part of the abdomen, with their distressing consequences, can be almost completely eliminated by the use of carefully made anatomic incisions. As a rule busy surgeons are impatient to reach the diseased organ and resent the extra time and attention necessary to make the previously described anatomic incision. But the ease of closure, the feeling of security in regard to the wound and the added comfort of the patient more than compensate for the extra effort.

NOTE—Since the presentation of this paper at the San Francisco session we have discovered one small postoperative hernia in a lateral transverse incision which was drained following removal of a suppurative gallbladder.

#### ABSTRACT OF DISCUSSION

DR. R. L. SANDERS, Memphis, Tenn. The authors report a 31 per cent mortality following abdominal wall disruptions in their series of cases. A review of the literature a few years ago revealed an average of 39 per cent mortality in a large series of cases reported from a half dozen of our largest hospitals. A follow up of my own cases showing a too high percentage of postoperative hernias led me to try the transverse incision in the upper part of the abdomen. My results have been satisfactory and coincide in general with those reported by Drs. Singleton and Blocker. They discussed the causes for wound disruption and postoperative hernia, calling attention to all the important factors involved. They have emphasized the need for a proper anatomic incision. The busy surgeon in his effort to reach the disease within does not take sufficient time to make the anatomic approach. This splendid presentation should cause us to stop and think, for it may be the means of avoiding future catastrophes. In 1930 I made a study of 500 cases of cholecystectomy to determine the incidence of postoperative hernia. A large percentage of the wounds were drained. To my amazement, a hernia had developed in almost 10 per cent of them. It would probably surprise all surgeons if a similar follow up were made. Some type of transverse incision by way of the anatomic approach may be the answer to the problem of wound disruption and postoperative hernia. During the past five years I have been using several modifications of the transverse approach and to date have done 250 cases. As mentioned by the authors, Dr. Sloan was among the first to use the transverse principle without division of the muscles. I think Drs. Singleton and Blocker have modified the incision to great advantage. I find the incision a little tedious to make but easy to close. When the linea alba is divided the exposure is excellent, but if infection supervenes it may weaken at that point and produce a bulge later. I am convinced that the modified anatomic approach shown by the authors has merit.

DR. ALTON OCHSNER, New Orleans. The authors have shown by their statistics the value of transverse incisions. It is interesting in reviewing these statistics to see that 85 per cent of the disruptions they have had at the John Sealy Hospital occurred in the lower abdominal incisions, which is contrary to the results obtained in most institutions. Drs. Singleton and Blocker used the transverse incision in upper abdominal operations. My experience is limited to the lateral transverse, which I learned from Dr. Singleton, and it has been gratifying to see the exposure which I could get following this operation. Dr. Sanders called attention to the delayed healing which may be the result of infection, which of course delays healing, and also the use of inadequate suture material, which he aptly stressed. I should like to emphasize the importance of the use of silk. The authors minimized the importance of silk, I think, rather incorrectly. I began using silk

in persons who were debilitated, such as patients with carcinoma. I now use silk much more extensively. I feel that silk is particularly indicated in cases of infection. Ordinarily one would think of not using silk in the presence of an infection but I believe that in cases in which healing is delayed and in which rupture is likely to occur its use is especially indicated. If one does use silk, let me reiterate the points which Professor Halsted emphasized many years ago. One must use fine silk, only interrupted sutures are to be used and the knots cut short, and only small bits of the tissue are caught in the stitch. In spite of the teachings of Halsted and Whipple concerning the proper use of silk, most surgeons when beginning to use silk use it incorrectly and therefore obtain undesirable results. If one will use interrupted silk sutures, it is surprising how many frankly contaminated wounds and infected wounds will heal without any discharge. It is continuous silk in the presence of infection which is particularly dangerous.

DR C. R. STEINKE, Akron, Ohio. I want to ask the authors a question. In connection with the upper abdominal incision, they mentioned a good many hernias. My experience has been that many of these come from peptic ulcer, particularly perforated ulcers. I wonder whether the authors would give their suggestion how to overcome this and tell us what percentage of their hernias occur in perforated ulcer cases or operations on the duodenum and stomach. With the subcostal incision (Kocher), which I have been using a great deal recently, I have had good results and have never had a hernia although I have had a number of infections.

DR HUGH H. TROUT, Roanoke, Va. I cannot resist speaking of three points in which I have been particularly interested. The first is the use of silk. I have used silk for many years. In an effort to obtain a substitute for catgut I have worked with rayon and other cellulose compounds. Altogether I have done something over 300 experiments. As yet I have not been able to obtain an absorbable substitute. Most of us think the absorbability of catgut is regulated by either the tannic or chromic acid or size of the gut but there is a factor that the manufacturers as yet have not been able to control, namely the age of the animal from which the gut has been removed. For instance, if one kills an old ram of 8 or 10 years of age and takes his gut, twists it and tries to absorb it, one has a foreign body, no matter how small the material that is being employed. The third factor is one that Dr Harvey Stone spoke about at the recent meeting of the American Surgical Association, namely, the proper preparation of the patient. If debilitated patients in whom disruptions have occurred more frequently than in any other type of patient are properly prepared with transfusions as well as with chemical and water balance, I think one will find that no matter what type of suture or incision one uses there will be a decided decrease in the number of disruptions.

DR FRANK K. BOLAND, Atlanta, Ga. The manner of making the abdominal incision is an important factor in the complication which frequently becomes a catastrophe. Certainly the manner of closing the incision does not seem to make any difference in many cases, nor does the nature of the suture material. Not long ago the abdominal wound of a 6 year old boy, in whom I had used chromic catgut throughout, broke open on the sixth postoperative day with evisceration. Not a trace of the so called twenty day catgut remained. I suppose this was a case of allergic reaction. Probably such a result would not have occurred if I had used silk throughout. As mentioned by the authors, I believe one should give special attention to the transversalis fascia in closing abdominal incisions. It is a very stout tissue which sometimes is identified and sometimes not. Whenever recognized however, it should be included in the peritoneal suture or sewed separately. The commonest cause of disrupted clean abdominal wounds is failure to coapt the peritoneum completely. The slightest opening that remains between stitches leaves a loophole for the entering wedge of the omnipresent curiosity-seeking omentum, which may result only in an adhesion or may produce complete disruption. It is remarkable with what few symptoms a wound may break

open. Frequently the condition has existed for several hours before it is discovered. The patient makes no complaint, the chart looks normal and the trouble is first recognized when the nurse sees drainage on a heretofore dry dressing. Several years ago I removed the stitches, including through and through silkworm gut, from the wound of a stout woman whose gallbladder had been removed ten days previously and closed without drainage. The same night the wound disrupted with evisceration. An associate was called and promptly reclosed the wound, reinserting the silkworm gut sutures. I had heard nothing of the event when I visited the patient the next morning and called for the dressing tray to inspect the wound the day after taking out stitches. To my surprise the stitches were still present. I proceeded to remove them again about twelve hours after they had been put in the second time. The young doctor who had resutured the incision gave me the information with great excitement. We proceeded to strap the wound with adhesive plaster but the patient had no more trouble from it.

DR ALBERT O. SINGLETON, Galveston, Texas. I hardly think that operators appreciate the difference between some of the operative wounds we have described and the usual wound, particularly in the upper part of the abdomen. Here the lateral muscles are respiratory muscles and any coughing or vomiting puts a tremendous strain on them, and for that reason I do not believe that the posterior sheath of the rectus muscle ever holds in a vertical incision, except in the very smoothest convalescence and for that reason the postoperative hernia is apt to occur. The last upper vertical incision I made was six years ago in a doctor with a gangrenous gallbladder. He developed a cough, and the wound disrupted and I repaired it. He coughed more and it broke again, and I sewed it as best I could. A few days later I could see his intestine was under the skin and I put adhesive tape over his wound, and now he is walking around with a big hernia. We have had such remarkable satisfaction with a fairly large number of cases that I hardly see why any other incision should be used. The question of infection in perforated ulcers was raised. We have had these infected many times, but none of them failed to unite properly. I had one patient in whom I made the incision three times, finding anatomic structures easy to recognize and performing the operation just as well the third time as the first. Dr Ochsner called attention to the question of suture material, and that, of course, is a very active subject at the present time. There has been a revival in interest in the use of silk, and with the reputation that these men have for honesty it is difficult to ignore their claims. I am almost persuaded to use silk. I am reluctant to do so because I have had an apathy to silk and linen for a long time. I have felt that if they used the same care in the use of catgut as they used with silk, they could get very nearly the same results. It requires a more careful operation to use silk, much more so than to use catgut.

---

**Bernard's Rural Laboratory**—Bernard's chief relaxation every year was a holiday which he took during August and September at his birthplace at Saint-Julien. Even here he did not entirely abandon his scientific pursuits. He had installed a makeshift laboratory in a shed and there he was in the habit of spending his mornings. He had a few retorts for simple chemical analyses and the neighboring swamp of Rigodiere provided him with frogs. Sometimes he would collect these "Jobs of the physiologist," as he called them, on his afternoon walks and bring them home in his pockets. The farmyard also furnished him with material for observation. He was at one time much interested in the career of a hen which dutifully mounted the nest and went through the motions of laying an egg with great regularity. When she left, cackling, it was found either that there was no egg or an egg without a yolk. In reporting the case history of this bird to Dr Davaine, his personal physician, Bernard said that the hen finally languished and died and when he performed an autopsy he found that there was obliteration of the upper extremity of the oviduct and the ventral cavity was filled with yolks which had escaped from the ovary. Dr Davaine, who was writing a memoir on anomalies in eggs, passed on this communication from his friend and patient to the *Societe de biologie* in 1860—Olmsted, J. M. D. Claude Bernard Physiologist New York, Harper & Bros., 1938.

# SURGICAL ASPECTS OF HYPOGLYCEMIA ASSOCIATED WITH DAMAGE TO THE LIVER

FREDERICK A. COLLIER, M.D.

AND

HOWARD C. JACKSON, M.D.

ANN ARBOR, MICH.

One of the many important functions of the liver is concerned with carbohydrate metabolism. It is fairly well established that the liver makes and stores glycogen and liberates it to the blood stream as dextrose, through which mechanism the normal glycemic level is maintained. It has been shown that gross interference with the liver, such as surgical extirpation, massive destruction by poisoning or replacement of large amounts of liver tissue by tumor, greatly disturbs this function.

The experiments of Mann<sup>1</sup> on extirpation of the liver established the fact that this organ is absolutely essential to the maintenance of a normal blood sugar level. Several hours after total hepatectomy his animals had a definite train of symptoms on the basis of demonstrated hypoglycemia. Invariably the animals were temporarily restored to normal by intravenous injection of dextrose.

Recognition of the clinical state of hypoglycemia followed the introduction of insulin into diabetic therapy. Attacks of collapse and even coma were occasionally noted subsequent to the injection of insulin and were found to be associated with abnormally low blood sugar values.<sup>2</sup> Administration of dextrose restored the blood sugar levels to normal and promptly relieved the attacks. Familiarity with this condition soon led to the observation that similar states sometimes occurred without the stimulus of insulin injection. Harris<sup>3</sup> in 1924 first speculated on spontaneous hypoglycemia and offered the obvious hypothesis that the condition resulted from the overproduction of insulin within the body.

Normally the fasting blood sugar level ranges between 60 and 110 mg per hundred cubic centimeters. Values below 60 mg are usually considered abnormal and may be accompanied by symptoms.

The clinical manifestations of hypoglycemia are variegated and sometimes present bizarre pictures. Harris<sup>4</sup> has stressed the wide variations in the signs and symptoms of hypoglycemia. The milder attacks cause chiefly subjective manifestations, including sensations of extreme hunger, irritability and nervousness, fatigue, weakness, apprehension and blurring of vision. Trembling, profuse perspiration, pallor, tachycardia and palpitation may accompany these. In more severe attacks the reactions may simulate petit mal epileptiform seizures or the victim may appear to be intoxicated. Sometimes severe abdominal pain is noted. Loss of consciousness characterizes the most severe attacks, and the coma may be accompanied by convulsions. Sometimes objective neurologic disturbances are present. When consciousness is lost, the blood sugar value as a rule is below 40 mg per hundred cubic centimeters.

Undoubtedly hyperinsulinism does occur, but it is exceedingly difficult of proof, since there is no satisfactory method of determining insulin in the blood. Wilder and his associates,<sup>5</sup> in their carefully studied case of metastasizing carcinoma of the islet cells of the pancreas, first reported apparently proved hyperinsulinism. Biologic assay of the tumor and its metastases revealed the presence of insulin, and the histologic study of the tumor cells revealed the characteristics of islet cells. Since then, in a number of other cases pancreatic tumor has been found associated with attacks of hypoglycemia.<sup>6</sup> The tumor has for the most part been a small discrete adenoma, classified generally as carcinoma.

Disturbances of other endocrine organs have been shown to be responsible for hypoglycemic attacks. Anderson<sup>7</sup> has reported a case in which adrenal tumor (carcinoma) was associated with a pronounced hypoglycemic tendency. Pluriglandular endocrine disorders are sometimes associated with hypoglycemia, among other manifestations.<sup>8</sup> Cushing<sup>9</sup> as early as 1912 noted that pituitary disturbance may be accompanied by hypoglycemia.

In most discussions of the subject liver disease is considered among the possible etiologic factors, but the tendency has been to belittle the role of the liver in the etiology of spontaneous hypoglycemia. Undoubtedly this is partly due to the demonstration by Mann<sup>1</sup> of the tremendous reserve powers of the liver. It seems to have been the general feeling that any liver disease capable of causing hypoglycemic reactions must perforce be so extensive and destructive as to be perfectly obvious by its other manifestations and probably fatal.

Diffuse parenchymal damage of the liver has been found to cause hypoglycemia. Minot and Cutler,<sup>10</sup> studying carbon tetrachloride poisoning, found that among the striking results of massive damage to the liver was marked hypoglycemia. Cases of acute yellow atrophy associated with pronounced hypoglycemia appear in the literature.<sup>11</sup> Cross and Blackford<sup>12</sup> reported a case in which spontaneous hypoglycemia followed injury of the liver by arsphenamine. This case has become a classic reference in discussions of

the possible etiologic role of the liver in spontaneous hypoglycemia. Fatty degeneration of the liver associated with hypoglycemia in children has been discussed by Josephs<sup>13</sup>.

Nadler and Wolfer<sup>14</sup> reported a case of spontaneous hypoglycemia in which from 70 to 80 per cent of the liver was replaced by primary hepatic carcinoma. Despite careful antemortem studies and, later, post-mortem examinations no other cause than hepatic insufficiency could be found for the hypoglycemia. A similar case was subsequently observed by Crawford.<sup>15</sup>

In a publication by Collier and Troost<sup>16</sup> appearing in 1929, it was pointed out that disturbance of carbohydrate metabolism is present in various types of liver disease and can be demonstrated by as simple a procedure as the dextrose tolerance test. Observations were made on dogs partially dehepatized by repeated removal of large blocks of liver tissue and on a large number of patients suffering from various recognized diseases of the liver (cirrhosis, chronic biliary infections, arsenical hepatitis, syphilitic hepatitis and extensive carcinomatosis of the liver).

The conclusion was drawn that with marked injury to the liver the dextrose tolerance curve shows a fasting blood sugar level which is normal or low and that a hyperglycemia follows the ingestion of dextrose which is similar to that seen with diabetes mellitus. A most significant point was made at that time namely, that when a glycosuric patient is found to have a low fasting blood sugar level the disturbance in the carbohydrate mechanism is most likely to be on the basis of hepatic disease and the condition is not true diabetes. More recently, studies by Newburgh and Conn<sup>17</sup> on the association of diabetes and obesity have produced evidence to show that often a "diabetic" picture occurs on the basis of disturbed glycogen storage in the liver rather than as a result of pancreatic dysfunction.

There have been many discussions of the functions of the liver and of liver function tests.<sup>18</sup> It has been pointed out that the functions of the liver are multiple and that one or more may be disturbed while the others are carried on in normal fashion. The correlation with anatomic damage is not always obvious. The galactose tolerance test has become the standard procedure for measuring carbohydrate function. The dextrose tolerance test has been little used as a liver function test, generally being dismissed with the statement that it is influenced by too many extrahepatic factors to be of great value. Recently a comparison of various liver function tests carried out on the same patients was made by Curtis<sup>19</sup> and his co-workers. They found the dextrose tolerance test far more valuable as a measure of liver function than the galactose tolerance test, the former being positive in 90 per cent of cases of hepatitis and the latter in only 30 per cent.<sup>20</sup> Furthermore,

they defined what they considered a fairly characteristic response associated with liver disease. If the dextrose tolerance curve begins with a normal or low fasting blood sugar level, rises during the first and second hours to levels higher than normal and, finally, falls to hypoglycemic levels during the third, fourth or fifth hour, it is probably indicative of dysfunction of the liver. This type of response was shown by Collier and Troost<sup>16</sup> in their experiments on dogs following the resection of liver tissue at successive operations. These curves were based on observations for only three hours. If the tests had been carried to the five hour period, it is probable that hypoglycemic levels would have been reached. Clinical studies presented in the same article substantiated the experimental observation.

There is no doubt that severe disease of the gallbladder and bile ducts produces anatomic changes in the hepatic parenchyma. This is particularly true if biliary obstruction and infection occur together. Graham's<sup>21</sup> studies of biopsies of the liver demonstrated that inflammatory changes in the liver are a constant accompaniment of gallbladder disease. His work has been challenged but not disproved.<sup>22</sup> It has been supported by studies on experimental cholecystitis<sup>23</sup> and by a review of autopsy material by Mentzer.<sup>24</sup> Certainly there can be little doubt in the minds of those who have operated in many cases of long-standing cholelithiasis and cholecystitis that the gross and microscopic structure of the liver is often definitely altered by the disease.

It is our contention that liver function is also disturbed by disease of the gallbladder and biliary tract and that in certain cases disturbance of carbohydrate metabolism is marked, occasionally even to the extent of causing hypoglycemia. Studies of liver function in cases of gallbladder disease are not abundant. Graham<sup>21</sup> has used a dye test to measure the liver function of patients who are to have operations on the gallbladder and biliary tract and has frequently found evidence of impaired function. There have appeared in the literature a number of reports of diabetes mellitus associated with gallbladder disease which has been cured or improved by surgical correction of the disease of the biliary tract.<sup>25</sup> Rabinowitch<sup>26</sup> has employed the dextrose tolerance test in studying a large number of patients with gallbladder disease, and most of these showed abnormal hyperglycemic curves. It has usually been the assumption that such disturbances of carbohydrate metabolism are due to injury of the pancreas. We believe that this is not necessarily true and submit the opinion that such conditions are not true diabetes but rather disturbances of glycogen storage and release by the affected liver. Studies by Newburgh and his co-workers<sup>17</sup> have been made in several cases of gall-

20 The dextrose tolerance test should be performed after a preparation diet containing 300 Gm of carbohydrate, 80 Gm of protein and enough fat to meet the normal energy requirement has been administered for at least three days. The subject is then given 175 Gm of dextrose per kilogram of body weight after an overnight fast. Specimens of blood should be collected for five hours after the administration of dextrose.

bladder disease by respiration chamber methods and support this contention, showing that the carbohydrate is normally oxidized, as it would not be if the secretion of insulin were disturbed. Recently Curtis and his co-workers have performed liver function studies on patients with gallbladder disease and have shown disturbed function in a high percentage by employing eight different tests. Particularly interesting to us is the fact that for a high percentage of patients with gallstones and chronic inflammatory gallbladder disease the dextrose tolerance test was abnormal. Several of their patients suffered hypoglycemic attacks during the tests.

Discussions of hypoglycemia as a surgical condition have all been concerned with operative procedures on the pancreas. Insulin-producing tumors of the pancreas and hyperfunction of a normal-appearing pancreas have been thought amenable to attack. Considering the complex mechanism involved in carbohydrate metabolism, it seems unwise to assume hyperinsulinism as the cause of hypoglycemia when pancreatic tumors are not present. When tumors of the pancreas are present, they should be removed.

In considering the surgical treatment of hypoglycemia, it should be borne in mind that the liver is an essential organ in the carbohydrate mechanism. Diseases of the biliary tract cause changes in the structure and function of the liver. Despite the reserve powers the organ is known to possess, clinical disturbances of carbohydrate metabolism do occur, with damage compatible with life. In the past it has been considered that infection in the biliary tract involved the pancreas secondarily, thus influencing carbohydrate metabolism, in spite of the fact that examinations of the pancreas have never substantiated the alleged frequency of these changes. The following cases are presented to illustrate hypoglycemic states resulting from damage to the liver secondary to cholecystitis and cholelithiasis.

#### REPORT OF CASES

CASE 1—W. F., a white man aged 47, was admitted to the hospital May 2, 1935, complaining of spells of unconsciousness. He had been well until two years before admission. The attacks occurred at irregular intervals but averaged once a month. They usually came on early in the morning, while the patient was still in bed, and lasted from twelve to twenty-four hours. Although he had no recollection of what occurred at these times, he was not always comatose but showed instead great mental confusion and agitation. Frequently he vomited during attacks. Otherwise there were no gastrointestinal symptoms.

Examination at the time of the first admission revealed that the patient was undernourished but well developed. The heart and lungs were normal and the blood pressure was 130/85. There was a well healed epigastric scar on the right side but no other abdominal abnormality. Neurologic examination gave negative results. The results of lumbar puncture were normal, tests of the spinal fluid and a Kahn test of the blood were negative. Roentgenograms of the skull were normal.

The patient remained in the hospital nineteen days, receiving small doses of phenobarbital and suffering no attacks. He was discharged with the unsatisfactory diagnosis of periodic coma.

He returned to the hospital in January 1936. A letter from his physician stated that he had continued to have the attacks on an average of two to three times a month. His physician suspected an intracranial neoplasm since several times the attacks had been abruptly terminated by intravenous injections of 50 per cent dextrose.

Because of the history of recovery of consciousness following the administration of dextrose, hypoglycemic reactions were suspected and a dextrose tolerance test was performed Jan. 9, 1936, with the following results: fasting blood sugar level 61 mg per hundred cubic centimeters, one hour 226 mg, two

hour 234 mg and three hour 103 mg. A second test, performed January 20, gave identical results save that the fasting blood sugar value was 53 mg per hundred cubic centimeters.

On the morning of January 24 he was unresponsive and drowsy when the nurse attempted to rouse him. Specimens of spinal fluid and blood obtained simultaneously were reported to contain 14 and 18 mg of sugar, respectively, per hundred cubic centimeters. Forty cc of 50 per cent dextrose was administered intravenously, and halfway through the injection the patient's apathy and confusion disappeared and he appeared normal and alert. On two succeeding days similar reactions occurred during one of which the blood sugar level was 17 mg.

These studies appeared to establish the spells of unconsciousness as hypoglycemic reactions, but the dextrose tolerance curve had been of the diabetoid type except for the low fasting blood sugar value. Hepatic insufficiency was suspected, and the patient was subjected to thorough metabolic studies by Drs. Conn and Newburgh, including periods in the respiration chamber. In the respiration chamber he oxidized dextrose normally, and therefore he could not have diabetes mellitus. Fasting blood sugar levels were repeatedly low, but most interesting was a five hour dextrose tolerance test performed on January 27, after the patient had been maintained several days on a 1,000 calorie diet containing 50 Gm of available dextrose. The results were as

Chart 1—Graphic representation of the dextrose tolerance tests in case 1. The fasting levels are low and the earlier curves show marked initial hyperglycemia.

follows: fasting blood sugar level 40 mg per hundred cubic centimeters, one hour 145 mg, two hour 214 mg, two and one-half hour 168 mg, three hour 142 mg, three and one-half hour 111 mg, four hour 93 mg, four and one-half hour 82 mg and five hour 65 mg. Significant features were the low fasting level and the retardation of the return of the curve to normal.

Studies of the liver function showed evidence of severe damage to the liver. The blood bilirubin content was 2 mg per thousand cubic centimeters (indirect), and there was a brom sulphalein retention of 90 per cent and 70 per cent, respectively, on two occasions. Blood smears revealed macrocytosis. The serum protein levels were low. Cholecystograms showed slight filling of the gallbladder but were indeterminate for the presence of stones.

At length it was decided that operation was indicated because of the possibility of an islet cell tumor of the pancreas, though it was realized that the apparent severe liver disease might be responsible for the hypoglycemic tendency. Laparotomy was performed March 9. The pancreas was first explored through the gastrosplenic omentum and seemed normal in all portions. Further exploration revealed the liver to be moderately enlarged with the granular appearance of early cirrhosis. The gallbladder wall was greatly thickened, and its lumen contained frank pus and several very large calculi. The viscous was removed and a biopsy specimen of the liver taken.

Microscopic examination by Dr. C. V. Weller showed "active chronic purulent cholecystitis" and "biliary cirrhosis." The

specimen from the liver showed active chronic cholangiolitis, fatty infiltration and cloudy swelling

Immediately after operation the patient was given generous amounts of dextrose intravenously. He had no hypoglycemic crises. For several days he had a stormy time, because of hiccupping and a minimal pulmonary infection. A mild infection of the wound cleared up well, and he was allowed up on the twenty-fourth postoperative day. Dextrose tolerance curves made postoperatively are shown in the accompanying charts. After operation the patient was almost entirely relieved of his previous symptoms. Fasting blood sugar values even within the first two weeks were higher than they had been before operation. During the first few weeks after he became ambulatory, he occasionally had a few moments of mild confusion which might have been due to hypoglycemia. One and a half months after operation he had a typical hypoglycemic attack one morning when his breakfast was delayed, and he was promptly restored to normal by dextrose given intravenously. Numerous tests of the liver function and dextrose tolerance were made during the five month period the patient remained in the hospital for observation. At the end of this time the fasting blood sugar level, dye excretion, serum protein content and red cell volume were within normal limits. He returned at monthly intervals until his death April 1, 1937, reported at autopsy as due to coronary artery disease. In January 1937 there was only 10 per cent retention of bromsulphalein and the red blood cells appeared normal. On a low carbohydrate diet he was unable to maintain an adequate blood sugar level, showing signs of hypoglycemia after three days on a diet containing 50 Gm of available dextrose daily. On Feb. 12, 1937, with a normal diet, the fasting blood sugar level was 80 mg per hundred cubic centimeters. The improvement was gradual but definite, and after the first month and a half after operation there were no further attacks of hypoglycemia, except when the patient was on a greatly restricted carbohydrate diet (chart 1).

CASE 2—V R, a white married woman aged 49, came to the hospital Oct. 18, 1935, complaining of weakness in the left leg, roaring in the ears and constant hunger. During the previous five years glycosuria had been detected on several occasions. She had received rather irregular treatment for diabetes in a diabetic clinic, sometimes being on a low caloric reduction diet and at other times receiving small amounts of insulin. She had lost about 60 pounds (27 Kg) in weight over the five year period. Aside from hunger sensations, most intense just before meals, there were no gastrointestinal complaints.

Examination revealed that the patient was well developed, somewhat obese and in good general condition. There were bilateral nerve deafness and unexplained peroneal palsy on the left side. A small thyroid adenoma was present in the isthmus. The chest was clear, and the heart was not remarkable. The blood pressure was 110/84. The abdomen was flat, and there was no tenderness. The liver could not be felt.

The Kahn reaction of the blood was negative, the urine was normal and there was no glycosuria. The basal metabolic rate was plus 14. A dextrose tolerance test performed Oct. 21, 1935, showed a fasting blood sugar level of 72 mg per hundred cubic centimeters, a one hour value of 224 mg, a two hour value of 194 mg and a three hour value of 132 mg. X-ray examinations showed a normal gastrointestinal tract. Cholecystograms revealed a single large semiopaque calculus.

A diagnosis of diabetes mellitus was made on the basis of the dextrose tolerance curve, and the patient was placed on a 1,200 calory diet yielding 140 Gm of available dextrose. She did not show glycosuria, and no insulin was used.

During the next year she was seen at monthly intervals and gradually reduced her weight. Occasionally she had mild pain in the right upper quadrant. She was aglycosuric at all times, and the restrictions on her diet were gradually lifted. Toward the end of the year she began having attacks of "jitters," which usually occurred during midmorning or before meals. During these spells she would become agitated, tremble violently, break into profuse perspiration and have a sense of intense hunger. Ingestion of food always brought immediate relief. Nov. 3, 1936, another dextrose tolerance test was performed, hypoglycemic reactions being suspected. The results were as follows:

fasting blood sugar level 86 mg per hundred cubic centimeters, one hour 180 mg, two hour 109 mg, three hour 58 mg, and four hour 56 mg. With this suspicious curve, the patient was placed on a diet containing 1,600 calories and 50 Gm of available dextrose, and daily fasting blood sugar values were determined. Six values ranged between 42 and 84 mg per hundred cubic centimeters and three of the readings were below 60 mg. During the next three months she was hospitalized twice, and extensive metabolic studies were performed. With a general diet the values for blood sugar all ranged between 70 and 80 mg per hundred cubic centimeters. With the diet containing but 50 Gm of available dextrose, fasting blood sugar values were usually below 50 mg. There was a moderate glycemic response to epinephrine, with a rise from 48 to 130 mg per hundred cubic centimeters after two hours. On a few occasions the patient had typical attacks of "jitters" when on a restricted diet. Other studies of the blood chemistry revealed normal blood protein values on several occasions. The blood bilirubin value ranged between 1.5 and 3 mg per hundred cubic centimeters (indirect).

At length it was decided to operate, the opinion being that the disturbed carbohydrate metabolism was on the basis of hepatic dysfunction. March 3, 1937, cholecystectomy and biopsy of the liver were performed. The liver was definitely enlarged,

MGS OF SUGAR PER 100 CC OF BLOOD

Chart 2—Graphic representation of the dextrose tolerance tests in case 2. The retardation of the return to normal levels was greatly diminished after operation.

the edges were rounded and the surface was finely granular. The gallbladder wall was moderately thickened, and the fundus was bound to the duodenum by adhesions. The lumen of the gallbladder contained one large stone. The specimen for biopsy of the liver was taken from the edge of the right lobe medial to the gallbladder. The pancreas was explored, seemed entirely normal and contained no visible or palpable tumors.

The gallbladder showed slight chronic cholecystitis with some cholesterosis of the mucosal folds. A solitary concretion measured 7 by 3 cm. The liver showed slight chronic interlobular hepatitis with lymphocyte infiltrations in the islands of Glisson. Fat stains showed an irregular distribution of fats, most marked storage being in the lobules which also showed the most marked inflammation.

She left the hospital without dietary restrictions. She has been seen several times since then for check-up examinations. In May 1937 she complained of being nervous and dizzy and very hungry at night. By September she had gained in weight from 140 to 176 pounds (63 to 80 Kg). During the interim she had noted extreme hunger many days at about 11 a.m. There had been no polydipsia or polyuria. After four days of a general diet a dextrose tolerance test was given with the following results: fasting blood sugar level 96 mg per hundred cubic centimeters, one hour 222 mg, two hour 100 mg, three hour 55 mg, four hour 61 mg, and five hour 71 mg. After five days of a diet containing only 50 Gm of available dextrose the fasting blood sugar level was but 30 mg

per hundred cubic centimeters. The patient was discharged again on a general diet. She has moved her home to another state since that time, and efforts to have her return for reexamination have been unavailing.

CASE 3—W B, a white man aged 25, came to the hospital March 23, 1938, complaining of a cutaneous eruption and "spells of nervousness." He had been in good health until the winter of 1932, when he had severe acne of the face and neck and almost simultaneously began to have "spells," during which he would feel dizzy and apprehensive, sweat excessively and have severe tremor of the hands. These spells would last from ten minutes to half an hour, and he would become very hungry. He discovered that if he could eat during the attacks his symptoms would cease, and he regularly obtained relief with food. The attacks occurred on an average of once a week during the five and one-half years and usually came on at night between 9 and 1 o'clock, three hours or more after his evening meal. During the period before admission to the hospital he also had four attacks with loss of consciousness, these taking place in 1932, 1934, 1935 and 1936.

Examination showed that the patient was well developed and well nourished and in apparently good general condition. There was severe acne cysticum of the face, neck and shoulders with

Chart 3—Graphic representation of the dextrose tolerance tests in case 3. After operation the curve very nearly approached the hypothetical normal and the initial hyperglycemia was of short duration.

many old scars. The heart and lungs were normal. The blood pressure was 136/88. The abdomen was flat, symmetrical and muscular, and there were no masses or spasm and no areas of tenderness. The extremities and genitalia were normal, and the neurologic examination gave entirely negative results.

Laboratory studies included examinations of the blood and urine, which proved to be normal. The Kahn reaction of the blood was negative, studies of the liver function gave normal results except for the dextrose tolerance curves. Bromsulphalein tests on April 7 and May 12 showed 12 per cent and 15 per cent retention of dye, respectively. On two occasions the values for serum protein were normal and the blood bilirubin content was 1 mg per thousand cubic centimeters (indirect). Morphologic studies of the blood showed no suggestion of macrocytosis. A galactose tolerance test performed May 14 showed no spill of sugar.

From the patient's history hypoglycemic crises were suspected, and he was admitted for study and observation. A dextrose tolerance test was done April 9, with the following results: fasting blood sugar level 67 mg per hundred cubic centimeters, one hour 250 mg, one and one-half hour 278 mg, two hour 188 mg, two and one-half hour 122 mg, three hour 53 mg and three and one-half hour 38 mg. At the time the three and one-half hour specimen was being drawn the patient lost consciousness and had a generalized tonic and clonic convulsion. He was promptly revived with 10 cc of 50 per cent dextrose given intravenously.

Four days later another dextrose tolerance test was performed. Two hours and thirty-five minutes after the test was started he again became unconscious and had a convulsion. The value for blood sugar five minutes before had been 41 mg per hundred cubic centimeters.

In the meantime the patient received treatment for his acne which showed some improvement. April 18 cholecystograms showed faint visualization of the gallbladder and a single non opaque calculus. After preparation with a diet containing 300 Gm of carbohydrate for three days, another dextrose tolerance test was done on May 15 (chart 3), with the following results: fasting blood sugar level 84 mg per hundred cubic centimeters, one half hour 162 mg, one hour 214 mg, one and one half hour 230 mg, two hour 152 mg, two and one half hour 65 mg, three hour 41 mg, four hour 58 mg and five hour 63 mg.

It was decided that laparotomy and cholecystectomy should be performed, and operation was done May 18. The pancreas was carefully explored through the gastrocolic omentum and appeared normal in all respects. No tumor could be found. The gallbladder wall was thickened, and the gallbladder was removed. The liver did not appear grossly abnormal but a specimen was taken for biopsy.

Examination of the tissue was made by Dr. L. F. Catron. There was a rounded cholesterol calculus 1.5 cm in diameter. The gallbladder wall showed slight active chronic cholecystitis with lymphocyte infiltration beneath the mucosa. The specimen from the liver showed many highly vacuolated cells, probably glycogen vacuoles, and small lymphoid cell infiltrations in the portal tracts.

The patient's postoperative course has been entirely satisfactory to date. He began eating well from the general house diet on the fifth postoperative day. On the tenth postoperative day he was placed on the diet, containing 300 Gm of carbohydrate, used as a preparation for the dextrose tolerance test and on the fifteenth postoperative day, a dextrose tolerance test was performed, with the following results: fasting blood sugar level 75 mg per hundred cubic centimeters, one half hour 136 mg, one hour 186 mg, one and one half hour 153 mg, two hour 107 mg, two and one half hour 78 mg, three hour 70 mg, four hour 62 mg and five hour 74 mg.

#### COMMENT

These cases are examples of severe and moderately severe hypoglycemia. The patients presented chronic cholecystic disease associated with cholelithiasis, the first had severe involvement and the others milder involvement. Biopsy revealed accompanying inflammatory changes in the liver parenchyma in each case. Dextrose tolerance tests were performed in each instance before and after operation. Dextrose tolerance curves made before operation showed variations from normal which indicated damage to the liver as judged by the criteria of Collier and Troost. Studies after operation showed a return toward normal. In none of the cases was there any abnormality of the pancreas which could be determined at operation. In the first two cases, studies with the respiration chamber were carried out before operation, as reported elsewhere by Conn and Newburgh,<sup>28</sup> showing that carbohydrate was oxidized normally and thus disproving the possibility of oversecretion of insulin. All three patients had symptoms caused by hypoglycemia which were modified by removal of the gallbladder.

It is of course too early to assume permanent improvement in the third case, but the patient presented a typical history of hypoglycemic attacks and surgical exploration revealed a normal pancreas.

The modification of the hypoglycemic tendency by operation in these cases was not as dramatic as that seen when pancreatic adenomas are removed. Instead of a sudden return to normal, after cholecystectomy

there was a gradual improvement. In analyzing the curves of the dextrose tolerance tests, one sees that the most definite change after operation was the diminished tendency to prolonged hyperglycemia following the ingestion of dextrose. In other words, the retardation of the return of the curve to normal levels was lessened. In the later stages of the tests the tendency to hypoglycemia persisted.

Regardless of the exact physiologic and biochemical processes, these cases are interesting since they illustrate a cause of hypoglycemia quite definitely not due to oversecretion of insulin. They illustrate another of the possible complications of chronic disease of the gallbladder and bile ducts and demonstrate that carbohydrate metabolism may be seriously disturbed by the accompanying hepatitis and cholangiolitis. The fact that such disturbances may occur is another reason for urging early operation on the diseased gallbladder, especially since the return of carbohydrate metabolism to normal may be slow and perhaps never complete.

Also we believe that these cases are important since they call to mind a cause of spontaneous hypoglycemic states as yet unconsidered. The liver disease was definite but not as destructive as has been present in previously reported cases of hepatic hypoglycemia. We believe that chronic cholecystitis and cholelithiasis with the accompanying changes in the liver must be added to the causes of extrapancreatic hypoglycemia.

#### SUMMARY

Hypoglycemia is a definite clinical state which in its more severe degrees has usually been assigned to hyperinsulinism.

The liver plays an important part in carbohydrate metabolism, and there is indubitable evidence that severe damage to the liver may cause hypoglycemia.

Gallbladder disease is associated with definite structural changes in the liver, and there may be accompanying changes in the liver function especially in the role of carbohydrate metabolism.

Dextrose tolerance curves in three cases of hypoglycemia with characteristic symptoms due to liver damage from gallbladder disease presented definite abnormalities before operation and a return toward normal after operation.

Possible profound and long-enduring disturbances of the carbohydrate metabolism may result from long-standing gallbladder disease, and this is an additional reason for early operation on the abnormal gallbladder.

We feel that the dextrose tolerance curve has a definite value in determining the carbohydrate function of the liver.

#### ABSTRACT OF DISCUSSION

DR EMILE F. HOLMAN, San Francisco. The authors are to be commended for presenting evidence of the altered functioning of the liver in the presence of a diseased gallbladder. Their observations make mandatory more careful preoperative preparation of any candidate for operation on the gallbladder in whom damage to the liver is probably present. An important precaution is the necessity of counteracting the immediate preoperative deprivation of food and water by mouth that is part of the routine preparation for a general anesthetic in any major surgical procedure. Elective abdominal operations are usually performed after a fasting period of from fifteen to eighteen hours. We have in our clinic for some years stressed the necessity of administering 1,000 cc. of 10 per cent dextrose solution intravenously in the two hours before the operation. There is no question, in the minds both of the anesthetist and of the surgeon, that patients so prepared withstand the ordinary

operation much more effectively and, when necessity arises, more prolonged procedures are possible. As to the mechanism whereby the removal of a gallbladder containing one stone and exhibiting normal function by cholecystogram can affect the carbohydrate metabolism of an organ like the liver, which shows such tremendous reserve in its function of regulating carbohydrate metabolism, I am not clear. Perhaps better regulation of food intake after operation accounts for this improvement. I expect further observations by Drs. Collier and Jackson to bring new light on the intricate subject of carbohydrate metabolism.

DR FRANK N. ALLAN, Boston. Since the syndrome of spontaneous hypoglycemia was first recognized it has offered difficulties in regard to both diagnosis and treatment. The diagnosis would seem simple, but there is more to be considered than just blood sugar tests. The situation is complicated by the fact that there is considerable variation in the normal range of the blood sugar level. One can never positively attribute symptoms to hypoglycemia unless one has actually demonstrated that the blood sugar is low at the exact time the symptoms are present and that elevation of the blood sugar results in disappearance of the symptoms. If one has an opportunity to study the case only in the interval between symptoms a sugar tolerance test may give helpful information, but care is needed in the interpretation of the blood sugar curve. The administration of dextrose may provoke, after the initial rise, a terminal fall in blood sugar to 60 or 50 or even less in many normal persons. The diagnosis of hypoglycemia and hyperinsulinism is often wrongly made on this observation alone, because of failure to recognize it as simply an exaggeration of a normal physiologic response. The cases described by the authors undoubtedly presented pathologic hypoglycemia, but the cause of the hypoglycemia in such cases cannot be determined by any simple means. The experience of Drs. Collier and Jackson has led them to believe that a sugar tolerance test resulting in a blood sugar curve with a high peak may indicate hepatic origin, yet this rule cannot be followed invariably. I have seen this type of response in cases in which hypoglycemia was due to hyperinsulinism with islet tumor. This was true early in the course of the first case of islet tumor which I had the opportunity to study and report in collaboration with Wilder, Power and Robertson more than ten years ago. Dietary regulation will overcome mild hypoglycemic symptoms which may be considered physiologic, but the severe symptoms, such as loss of consciousness and convulsions, are often refractory to any conservative method of treatment. It is gratifying to learn from the authors that surgery offers another means of relief. My chief, Dr. Frank Lahey, has often emphasized the menace of damage to the liver resulting from biliary infection associated with gallstones, and almost every surgeon holds the same opinion. Yet far too often we medical men maintain a complacent attitude with regard to gallstones. The demonstration by the authors shows further the importance of early diagnosis and early operation for gallstones, before there has been damage to the liver which may result in serious ill effects, including hypoglycemia.

DR T. L. ALTHAUSEN, San Francisco. Several years ago I studied clinically and experimentally the influence of hepatic damage on certain phases of carbohydrate metabolism, and some of these studies have a direct bearing on the paper of Drs. Collier and Jackson. Rabbits were injected daily for periods up to two years with small doses of one of several hepatic toxins (phosphorus, chloroform, manganese chloride). At intervals the tolerance of these animals to dextrose was tested. In the early stages of hepatic injury the animals were found to exhibit better than normal tolerance to dextrose, which I interpreted as an irritation phenomenon. Later the tolerance to dextrose became progressively impaired. However, several rabbits when tested only a few hours before death again showed a very low blood sugar curve following the test. The same was observed also in animals during convalescence from a single large dose of any hepatic toxin. Essentially the same variations of tolerance to dextrose were observed in patients suffering from diseases of the liver making it extremely difficult to interpret the clinical significance of such tests in any given case. I also found that hepatic insufficiency produced in rabbits a consistent and in patients an occasional, lowering of the fasting

blood sugar. On the other hand, abnormal hypoglycemia after administration of insulin and dextrose in both rabbits and human beings with hepatic damage was a constant enough observation to recommend this procedure as a liver function test for clinical use. I agree with the authors of this paper with regard to the advisability of preoperative liver function tests whenever hepatic insufficiency may be suspected from the nature of the disease or from other clinical indications. At the University of California Hospital, through the cooperation of the Departments of Medicine and Surgery, the operative mortality from cholecystectomy has been reduced from 10 to 2 per cent, largely by the preoperative use of liver function tests. In cases in which considerable hepatic insufficiency was discovered, the operation was either not undertaken or was postponed until after a period of preparation with a high carbohydrate diet and other measures.

DR FREDERICK A COLLIER, Ann Arbor, Mich. I want to thank those who have discussed this paper. They have added a great deal to the subject that Dr Jackson and I could not give. I realize that these cases I have presented are not entirely conclusive but I do think that we have evidence that hepatic injury can be produced by disease of the gallbladder and that hypoglycemia may result. It is our hope that this presentation may stimulate others to make further studies in this field. Dr Allan stated the crux of the matter when he said that he felt that disease of the gallbladder in time may cause harm to the liver. I feel that we have drawn up another indictment against the so-called silent stone. I do not think any stone is ever silent. I think that when stones are present in the gallbladder they should be removed. From the point of view of the surgeon we have presented one more bit of evidence that we should all be more radical in our operative attack on patients who have gallstones.

## Clinical Notes, Suggestions and New Instruments

### AGRANULOCYTIC ANGINA

REPORT OF A CASE DUE TO CAUSALIN

V. J. DARDINSKI, M.D., Ph.D. AND E. STUART LADDANE, M.D.  
WASHINGTON, D. C.

The Council on Pharmacy and Chemistry of the American Medical Association suggested the probability that the drug "causalin," recommended for the treatment of arthritis, contains aminopyrine.

We feel that this drug was responsible for the production of agranulocytosis in the case presented here.

#### REPORT OF CASE

J. J. E., a white man aged 65, was admitted to the Georgetown University Hospital Dec. 6, 1937, and died the same day. His chief complaint on admission was "sore throat." Two weeks prior to admission he had a "cold" from which he apparently recovered. One week prior to admission he had a chill with fever. He thought that this condition was a recurrence of his previous "cold." Six days prior to admission he first noticed a sore throat, which was treated locally with mercurochrome. Three days before admission ulcerations were found in the pharynx, which was markedly edematous and congested. Gradually but rapidly he became weaker until the day of his admission, when he was very toxic and semicomatose.

Physical examination revealed a markedly injected hyperemic pharynx with ulcerations on the posterior wall of the pharynx. The tonsils were small. The cervical lymph glands were enlarged bilaterally and were very tender. The heart rate was 120 per minute and irregular. The blood pressure was 65 systolic, 50 diastolic, and the temperature was 104 F. The patient was moribund and died soon after examination.

Examination of the blood showed hemoglobin 60 per cent, red blood cells 3,150,000, white blood cells 500. The differential picture showed polymorphonuclear leukocytes 29 per cent, lymphocytes 70 per cent, myelocytes 1 per cent. Urinalysis showed specific gravity 1.022, albumin 4+, sugar 3+, hyaline casts +, red blood cells +, leukocytes +.

A history obtained from the family revealed that the patient had been taking causalin tablets for his arthritis for the past four months. The definite number of tablets taken could not be determined, but it was believed that he had taken well over 100.

### A METHOD FOR THE DARK FIELD EXAMINATION OF PUS FOR SPIROCHAETA PALLIDA

IRON, IRIFUMA, M.D., PHILADELPHIA

The visible contamination of a specimen of serum with cellular elements and debris renders that specimen almost useless for direct dark field examination for *Spirochaeta pallida*. Various techniques have been devised for the preparation of a suggestive lesion in order to obtain a satisfactory specimen for dark field examination,<sup>1</sup> but no method has been previously developed to convert a pus or blood contaminated specimen into one suitable for adequate dark field study. Carley<sup>2</sup> advocates the dark field examination of urethral discharge when there is any suspicion of syphilis but states that this is not possible in all cases. In fact Dr. John H. Stokes<sup>3</sup> in commenting on the detection of syphilis in a urologic clinic stated "A gonorrheal discharge contains so many pus cells that dark field examination is unsatisfactory as from a heavily blood contaminated specimen. The white blood cell does not undergo lysis as easily as does the red but experimentation may possibly develop methods which will remove the white blood cell factor from the field, permitting an examination of a relatively clear urethral discharge." Stimulated by this suggestion I undertook to develop a method for the removal of the blood cell from the pus contaminated specimen.

The literature while it does not describe a definite method, does give pertinent leads which I have followed in the development of the method. Riehl<sup>4</sup> and Schereschewsky<sup>5</sup> in 1919 were the first to use glass capillary pipets, sealed by fusion in a flame, to preserve specimens of serum. Riehl<sup>4</sup> found recognizable spirochetes as long as fourteen days after collection. Zurhelle<sup>6</sup> and Strempel<sup>7</sup> demonstrated that motile organisms may be found in dead tissue debris seven days after collection. Based on this work, Stokes and Ewing<sup>8</sup> in 1926 described an outfit for physicians to collect serum for dark field examination. Mahoney and Bryant<sup>9</sup> used fine straight glass capillary pipets about 8 cm. in length and of a constant bore. Jauson<sup>10</sup> reported that *Spirochaeta pallida* in washings of the vagina can be thrown down and concentrated for dark field examination by centrifugation for from forty five to sixty minutes at 9,000 revolutions per minute, a high speed. Also it is known that the Wassermann blood serologic test makes use of the fact that the cellular elements of the blood can be rapidly thrown down by centrifugation at low speeds. As a result of these hints from the literature, it occurred to me that it might be feasible to centrifuge capillary tubes filled with pus at a low speed and thus obtain a cleared specimen of serum for dark field examination.

A number of fine straight glass capillary tubes about 12 cm. in length and of a constant bore were prepared. Sections of

Read before the Thirtieth Annual Meeting of the Undergraduate Medical Association, University of Pennsylvania, April 20, 1938. University of Pennsylvania School of Medicine, John H. Stokes, M.D., Director.

The urological and dermatological staffs of the Hospital of the University of Pennsylvania and Dr. W. G. Turnbull and the staff of the Genito-Urinary Dispensary of the Philadelphia General Hospital gave their heartiest cooperation to the author. This work was carried out under the guidance and advice of Dr. Herman Beerman.

glass tubing 6 mm in outside diameter and 13 cm in length, sealed at one end, were prepared as receptacles for the fine glass capillaries. Undiluted gonorrheal urethral discharge was collected from dispensary patients of the Urologic Outpatient Department of the Hospital of the University of Pennsylvania. A number of the fine tubes were filled by capillarity with this discharge and one end of each tube was sealed by fusing in a small flame. The tubes were then placed in the receptacles and centrifuged in an international electric centrifuge, size 2, at various speeds and for various lengths of time. The lowest speed and the shortest time necessary to throw down all the cellular elements and leave a clear column of serum in the upper portion of the capillary tube proved to be 1,000 revolutions per minute for ten minutes. This speed was easily obtained with a small portable hand centrifuge, which was later substituted for the electric centrifuge.

A syphilitic rabbit testicle emulsion containing *Spirochaeta pallida* demonstrable by direct dark field examination was mixed with gonorrheal urethral discharge so that the spirochetes could not be demonstrated by direct dark field examination of the mixture. Capillary tubes were then filled with this mixture and centrifuged at 1,000 revolutions per minute for ten minutes. The tubes were filed and broken just above the line of separation of the sediment from the clear supernatant serum, which, after expulsion by pressure from a small rubber bulb, was subjected to direct dark field study. This examination readily revealed motile spirochetes.

This method for the dark field examination of pus for *Spirochaeta pallida* was then tested clinically by applying it to a series of forty patients with acute gonorrheal urethritis, all with typical purulent discharges. These patients were from the urologic outpatient department of the Hospital of the University of Pennsylvania and from the Genito Urinary Dispensary of the Philadelphia General Hospital. The capillary tube was applied directly to the pus appearing at the meatus of the penis and allowed to fill by capillarity. It was then sealed, centrifuged and cut as described, and the cleared serum examined for *Spirochaeta pallida*. Each patient was in addition studied for the presence of a syphilitic infection according to the method of Friedman and Mazer.<sup>10</sup> This method includes history, physical examination, serologic study and serologic follow up for three months.

The results of the clinical application of the method for the dark field examination of pus for *Spirochaeta pallida* are as follows:

In thirty-seven cases the urethral discharges were negative for *Spirochaeta pallida*. The history and physical examination were negative for syphilis. Blood serologic studies were negative at the time of the first visit and at the time of follow-up examinations.

In one case the urethral discharge was negative for *Spirochaeta pallida*. The history and physical examination were negative for syphilis. A blood serologic study was negative at the time of the first visit but positive fifty-two days after the onset of the discharge, sixty-two days after exposure.

In two cases the urethral discharges were positive for *Spirochaeta pallida* only after the specimens had been centrifuged. The spirochetes could not be demonstrated by direct dark field examination of the pus. The history was negative for syphilis. Physical examination in both cases revealed a slightly indurated prepuce and moderate circummeatal excoriation of the glans penis. There was a profuse gonorrheal urethral discharge. A blood serologic study in both cases was positive at the time of the first examination.

This method was also applied in the Clinic of Cutaneous Medicine and Syphilology of the Hospital of the University of Pennsylvania to one patient with a penile lesion suggestive of a chancre. This lesion bled freely when an attempt was made to obtain a specimen of serum for dark field study. The bloody serum was collected in the capillary tube and centrifuged. *Spirochaeta pallida* was found in the first field examined. Dark field study of the uncentrifuged serum was also positive but only after long search.

Finally, this method was applied in the Clinic of Cutaneous Medicine to one patient with an irretractile indurated prepuce from under which a thick creamy discharge of pus could be expressed. Dark field examination of the pus was negative for *Spirochaeta pallida*. Pus examined after centrifugation in the capillary tube revealed many spirochetes.

#### SUMMARY AND CONCLUSIONS

1 A method has been developed for the dark field examination of pus for *Spirochaeta pallida*.

2 A limited clinical application of the method demonstrated *Spirochaeta pallida* in two cases of acute gonorrheal urethral discharge, one case of bloody serum from a penile lesion and one case of thick pus from under an irretractile indurated prepuce—this being the only method for establishing the diagnosis, in this case, of a primary infection with *Spirochaeta pallida*.

It did not demonstrate *Spirochaeta pallida* in thirty-seven cases of acute gonorrheal urethral discharge which were syphilologically negative.

It failed to demonstrate *Spirochaeta pallida* in a patient with acute gonorrheal urethritis in whom blood serologic tests were positive for syphilis sixty-two days after the last sexual contact and fifty-two days after the onset of the discharge.

3 This method makes possible the dark field examination for *Spirochaeta pallida* of small amounts of any body fluid, exudate or discharge susceptible of collection in a capillary tube.

4 The method is a simple procedure requiring a minimum of laboratory equipment and can be performed in as short a time as fifteen minutes.

#### ARTIFICIAL CONCENTRATION OF TEST SERUMS IN BLOOD GROUPING

M C TERRY M D KNOXVILLE IOWA

In a recent issue of THE JOURNAL Hoxworth and Mahoney<sup>1</sup> call attention to the importance of using only test serums of high agglutinin titer in the determination of blood groups and report their success in concentrating inferior serums by the lyophile process to a titer considerably higher than that proposed by Coca<sup>2</sup> for a first grade reagent for this purpose.

Occasionally, as has been Hoxworth and Mahoney's good fortune, serums will be found which equal or exceed the requirements for Coca's grade I, but most of them fall below that standard, and methods for raising the titer of low grade serum are, as Hoxworth and Mahoney say, highly desirable.

The method of concentration by alternate freezing and thawing<sup>3</sup> to which Hoxworth and Mahoney refer, was originally employed by O'Meara,<sup>4</sup> a fact not known to me at the time I made the report, due acknowledgment of O'Meara's priority was made in a subsequent issue of the *Proceedings of the Society of Experimental Biology and Medicine*.

I now present a third method of such simplicity that I am quite prepared to learn that here again some one has anticipated me. The method is that of pervaporation devised by Kober<sup>5</sup> in 1917 but apparently pretty much neglected until it was revived by Farber<sup>6</sup> in 1935. I shall give an example from my work.

A type A' serum which fell short of Coca's grade II was put in a cellophane dialysis tube three-eighths inch in diameter and placed in front of a 16 inch electric fan. The height of the column was 16 cm. On making this or the like experiment for the first time one is astonished at the speed with which evaporation goes on, in the example given the 16 cm column went down to 4 cm in two and one-half hours, and the concen-

tration of the agglutinin was such that the product exceeded the requirements for Coca's grade I, a 1:4 dilution causing macroscopic clumping in ten seconds, a 1:8 dilution in twenty seconds.

The lyophile apparatus is rather expensive. The cellophane tubing used in this example costs less than 5 cents.

I know from an experiment with anti-sheep hemolysin that serum can be so far evaporated by Kober's method that when dried in the 37 degree incubator it may be ground up in a mortar to a fairly fine powder which, at least in the case of that hemolysin, keeps its specific property and approximate titer for a long time. It would not seem worth while to go so far with serum for routine blood grouping, but agglutinins for the M and N factors might be made more available in this way.

### A PROGRAM FOR EARLY AGGRESSIVE TREATMENT OF PULMONARY TUBERCULOSIS

CLINICAL LECTURE AT SAN FRANCISCO SESSION

CASPER F. HEGNER, M.D.  
DENVER

Pulmonary tuberculosis is a chronic systemic disease with a decided tendency to heal. The chronicity, inherent tendency to heal and curability are due to a beneficent auto-immunization. Were this not true the human race would long since have vanished. This chronicity, when the disease is untreated, inadequately treated or unrecognized, is responsible for its continuous contagion and universal distribution, for a reducible economic waste and disability and for a certain irreducible mortality rate.

A program for early aggressive treatment of pulmonary tuberculosis is properly initiated by the diagnosis of the disease in the earliest possible stage. During the period of inception and the early stage more can be accomplished by less therapy than at any time thereafter.

The inception of tuberculosis is subtle, the onset insidious and the early progress stealthy and so devoid of symptoms that the host is taken unawares.

When the disease first becomes clinically manifest it is usually not in the early stage but is well developed, with focal tissue changes more or less advanced.

The earliest general clinical symptoms due to altered physiology are not positive. They are largely inferential. The earliest local signs dependent on pathologic changes are positive. These are differential.

The preclinical and early clinical stages are often overlooked even by expert examiners. Errors in diagnosis are more frequently made by the less expert and those who are not tuberculosis minded. Physicians must become tuberculosis minded and appreciative of their fallibility. The usual methods of examination for early tuberculosis have definite diagnostic limitations.

However experienced, one cannot place complete reliance on one's skill in auscultation and percussion. Additional corroborative methods of examination must be used, the tuberculin test must be used with children and in all suggestive cases fluoroscopic examination

must be done and roentgenograms of the chest made. To be dependable x-ray examinations must be interpreted by experienced physicians or experts in pathologic changes of the lungs as depicted by x-ray examination.

In borderline cases the x-ray examination cannot determine the grade of activity of a tuberculous lesion. It does portray more accurately than any other diagnostic procedure the presence and extent of lesions.

It is obligatory to check the physical signs with those shown by x-ray examination.<sup>1</sup>

The success of the antituberculosis campaign has been brilliant. Much remains to be accomplished before the disease is vanquished. The incidence of and the deaths due to pulmonary tuberculosis have decreased roughly 60 per cent in the last twenty years. The 40 per cent ratio of deaths to the number of cases has not changed materially notwithstanding the tremendous increase in hospitalization and sanatorium care and the advances made in the active treatment of the disease. The causes of this constant death ratio warrant critical analysis. The ratio is a challenge. An aggressive program of case and feeder finding by which the disease can be diagnosed and treated at its very inception, and isolation or control of those who wittingly or unwittingly, are disseminators of the disease, offer a most potent answer to this challenge.

The antituberculosis program in the past has been of necessity largely one of defense against active phases of the disease. One waited until the victims were well seeded with tubercle bacilli or for their lesions to become definite before beginning active treatment.

To wait for the disease to become clinically manifest is to wait too long. Procrastination compounds difficulties, augments the uncertainty of therapy, prolongs disability, increases expense, spreads infection and multiplies mortality.

Prophylaxis is certain, while cure is uncertain when the disease is fully developed and impossible in a fairly fixed percentage of cases. These facts are established by the convincing investigations and mass studies for case finding and tracing all contacts to the source of infection.<sup>2</sup> Though it is not always possible to trace the infection to its source, these surveys reemphasize the fact that every case of pulmonary tuberculosis originates directly or indirectly from some previous case. The reports further prove that early pulmonary tuberculosis, especially in adolescence and early adult life, the periods during which, in the majority of cases, the disease first becomes active, is commonly symptomless and hence frequently undiagnosed.

One must face facts. The antituberculosis campaign of the future to be fully effective must be not only one of defense but also one of offense. An aggressive campaign of case and feeder finding would attack the disease before the tubercle bacilli became seeded, and active therapy would be begun months or years before irreparable damage to the tissues had time to develop. It is easier to prevent than it is to cure destruction of tissue and complications.

The early recognition and treatment of the infected and control of the infectors is logical, economical and practical.<sup>4</sup> Patients with open tuberculosis must be isolated whenever possible. If sanatorium isolation is impossible, then the utmost should be done by a course of sanatorium treatment and instruction to control or render them innocuous. The contacts must be treated before they in turn have active open tuberculosis.

By such a program the incidence and life history of tuberculosis will become known and its methods of spread understood. Both the profession and the public will become sensitized to the importance of competent periodic health examinations, to the necessity of early diagnosis and to the advantages of early treatment. Thus fortified, many of the present problems in treatment and most of the weak points in the fight against tuberculosis will be overcome.

Tuberculosis is recruited from the ranks of those who are in apparent health. It is no respecter of class, creed or color and knows no geographic, political or social boundaries. A competent, efficient antituberculosis program must be one of stern defense and aggressive offense, coextensive with the distribution of the disease.

#### NECESSITY OF EARLY CASE FINDING

A campaign of early case finding, national in scope, and the isolation or control of bacilli breeders and disease disseminators will accomplish more than any other, if not all other, factors in the treatment and eradication of pulmonary tuberculosis.

This is a large and expensive program beyond the authority and means of private enterprise. One can participate in appointing qualified commissions to study and in organizing competent agencies to carry on this important work. Cooperation of the public with the profession is essential to the success of any health program. An enlightened public sentiment will support and later demand public health projects. Success in the control and elimination of one disease reacts favorably and forcefully on campaigns for the control of other diseases. A national health department is indispensable for the coordination of complex public health activities.

Conservation of public health and control of communicable diseases are the province of the federal government and its various subdivisions. They have the authority to make and enforce health regulations.

A national department of public health should promptly take up and vigorously extend nationwide compulsory mass surveys for case and feeder finding. Small groups of investigators within their limited means and scope have proved the importance and value of such surveys on a voluntary basis.<sup>5</sup> The trail has been blazed, the administrative set-up pioneered and the feasibility of the plan assured.

The treatment of the ill is not the jurisdiction of governmental agencies. This has been, is and should continue to be the prerogative of private physicians. The confusing of federal, state and civic obligations with private and professional affairs begets irresponsibility, inefficiency and distrust. This truth is more certain in the realm of therapy than in any other field of endeavor. Regimentation of doctors is possible though highly undesirable. Regimentation of therapy worthy of respect is impossible.

The requisites for an efficient aggressive program for the control and eradication of pulmonary tuberculosis are:

First in point of time and importance, an authoritative mass survey, national in scope, of case and feeder finding.

Second, continuous maintenance by the medical profession of a true appreciation of the character of the disease. It is expedient to consider tuberculosis more serious than the clinical symptoms indicate.

Third, early treatment. The earlier appropriate treatment is begun, the more consistently enforced by the physician and the more conscientiously followed by the patient, the more rapid and certain will resolution ensue.

#### EXPECTANT TREATMENT

The passive or expectant treatment of pulmonary tuberculosis is founded on the time-tried and proved principles of general rest, fresh air and wholesome food. To this honored triad, modern active treatment has added collapse therapy to secure local rest to the diseased lung. The therapeutic result will be proportionate to the degree, duration and timeliness of general plus local rest. This is true not only in the early stages of the disease but also in advanced stages and in cases in which the disease is resistant and demands some form of surgical aid.

Every patient differs in his local and general reaction to infection. The dose and degree of virulence of the infecting organism and the grade of susceptibility, which fluctuate from time to time, determine the clinical symptoms, the character and intensity of the pathologic changes and the course of the disease. The response to therapy likewise varies. The pulmonary lesions are an accurate index of the trend of battle between the tubercle bacilli and the resistance of the patient. The evolution of the local lesions must be as closely followed as is the general progress made by the patient in order to estimate, round by round, his ability to overcome the disease. The course and severity of the clinical symptoms do not constantly parallel the pathologic changes in the tissues. This lag in constitutional reactions is deceptive.

No one can deny the importance and value of expectant treatment in early stages or that in many cases it fails, without additional aid, to control the progress of the disease.

#### COLLAPSE THERAPY

General rest and expectant treatment should be tried for a reasonable time, a period expressed in terms of weeks. As long as favorable progress is made, one should defer active therapeutic measures. When favorable progress is not made or ceases, active measures to secure the added benefits of local rest by some form of collapse therapy are promptly indicated. Collapse therapy is not a substitute for any of the older forms of treatment, it is an invaluable supplement to these when after a reasonable trial they have failed, or in the light of experience are destined to fail, to reestablish a resistance balance against the disease.

The earlier a focus not controlled by expectant treatment is attacked by the appropriate measure for collapse, the more certain, rapid and favorable will be the effect and the fewer the complications.

One must obtain promptly the minimum collapse of the lung that is conducive to healing all the tubercu-

lous infiltration and cavitation.<sup>6</sup> A more extensive procedure than is needed to control the lesion should be avoided. Unnecessary destruction of tissue and of functioning lung parenchyma will be prevented.

A variety of mechanical procedures have been devised to control different stages of the disease. They all have definite indications and limitations. There is an optimum time for each procedure, which if not taken advantage of leads to more extensive operations.

Every patient who presents indications for more radical procedures of surgical collapse is a living example of failure, a failure of the physician to diagnose early, to appreciate the gravity of the disease and to institute promptly and continue rigidly appropriate conservative measures, a failure of the patient to cooperate or of the disease to respond to the expectant treatment, or a failure of the physician to resort early to less radical measures for collapse therapy. A favorable opportunity lost renders the general condition of the patient more serious and permits the development of complications or extension of the disease to irremediable stages.

Surgeons have learned the necessity of early operations in the treatment of cancer, the advantage of operating during the rising tide of reserve in thyrotoxic states and the diminished hazard in multiple stage operations in the case of properly prepared patients with prostatic disease. These lessons are equally applicable in the surgical treatment of pulmonary tuberculosis. Timely surgical intervention is truly conservative. Late operations are always of greater magnitude and danger and the results are not so satisfactory as those of early operations.

The purpose of collapse therapy is to secure local rest to the diseased lung, to prevent the development of restraining mechanical factors and to eliminate impediments to contraction of the diseased area of the lung. The objective of compression therapy is actively to compress the cavity or the cavity-bearing area of the lung and control resistant interposed lesions which interfere with contraction and healing. The advantages of timely collapse therapy are proved by the splendid results attained with progressive and otherwise hopeless conditions. Delay in the diagnosis of pulmonary tuberculosis has been and is the chief obstacle to the control of pulmonary disease. Delay in instituting graded collapse therapy compromises and may defeat all efforts to cure.

Successful collapse therapy for pulmonary tuberculosis is not merely a matter of technique. Important as this is, of greater importance is the choice of procedure, the time and the degree of collapse needed. There is no procedure yet devised that is universally applicable to the fluctuating phases of the disease. Each procedure must be graded to control the local lesion. This involves an understanding of the patient, who is always a standard surgical risk, a grasp of the mechanics of the thorax and the physiology of respiration, an estimate of the cardiac reserve and a knowledge of the pathology of all stages of the disease.

A surgeon should approach a case of pulmonary tuberculosis from a medical no less than from a surgical point of view. He should collaborate with the phthisiologist and the radiologist, who must become surgically minded. They must understand all phases

of the disease and the indications and possibilities of combinations of the two plans of treatment.

Competent surgical treatment without continued intelligent general medical care cannot cure. Adequate timely surgical treatment can and does render local conditions favorable for the orderly processes of healing to effect an arrest or cure.

Pulmonary tuberculosis demands medical supervision from its inception until it is clinically cured. Too often this fact is overlooked in the treatment of patients subjected to surgical collapse. The patient and sometimes his physician are deluded by the immediate improvement secured by surgical intervention. They relax in the care which is vital to making that improvement permanent. For a lasting cure it is obligatory that the patient continue for months after operation a graded rest regimen. Adequate prolonged collapse facilitates the permanent obliteration of cavities and the healing of pericavitary lesions by fibrosis. No operation can do more.

Before operative intervention is decided on, a review of the history and a careful complete examination of the patient should be made, a meticulous study of the evolution and the present status of the lesions in the lung, so graphically and chronologically recorded by a series of x-ray films, is imperative. The information obtained is of inestimable value in deciding what, if any, surgical intervention is indicated.

Select that procedure which will be most effective for the given stage. When possible employ revocable measures in ascending grades of severity, giving each procedure a reasonable period to prove its capacity to control the lesion. Note the progress by repeated physical examination and x-ray study. With contralateral lesions, and these are always present in some degree, the responsibility is augmented in proportion to the extent and grade of activity, one must proceed with caution, keeping well within the limits of respiratory and cardiac reserve.

When revocable measures are not indicated or have failed to control the progress of the disease, then irrevocable measures for selective compression are indicated. The least extensive surgical operation that will secure adequate compression is the operation of election. In many cases a sequence of procedures is neither indicated nor advisable. The character, location and extent of the lesion determines an operation of necessity. The general condition of the patient may and often does demand that it be performed in multiple stages. Better regret doing too little than mourn the death of a patient.

#### PROCEDURES

The procedures for collapse therapy are (1) artificial pneumothorax—unilateral, alternating or simultaneous bilateral, (2) intrapleural pneumolysis, (3) interruption of phrenic nerve conduction, temporary or permanent, (4) scalenectomy, (5) extrapleural pneumolysis with or without filling of the extrapleural space, and (6) thoracoplasty, partial upper or partial lower, as single stages or in sequence, with or without extra fascial mobilization of the lung, or complete, in multiple stages. The first four procedures leave the thoracic wall intact and with one exception (permanent phrenic nerve interruption) are revocable, the last two are compressing operations which alter the osseous structures of the thorax and are irrevocable.

<sup>6</sup> Dundee, J. C. End Treatment of Artificial Pneumothorax. New Use of Phrenic Anulsiion. *Am. Rev. Tuberc.* 25: 469 (April) 1932.

*Artificial Pneumothorax*—The introduction of artificial pneumothorax marked a transition from the time-honored passive and expectant treatment to the modern active or aggressive therapy of pulmonary tuberculosis.<sup>7</sup>

Wherever the efficacy of timely pneumothorax is fully appreciated it is recognized as the most valuable adjunct to phthisiotherapy. It has become a standard form of treatment in modern sanatoriums everywhere, curing or arresting the progress of the disease not possible by expectant treatment alone.

Induced pneumothorax is the spearhead of a line of surgical attack to secure added local rest to the diseased area of the lung by procedures graded from early relaxation and temporary collapse to firm irrevocable compression.

It is unfortunate that these gradations are not generally recognized and understood. An appreciation of the gradation principle of collapse therapy is of utmost importance in the modern treatment of pulmonary tuberculosis. The advantages of timely graded collapse therapy are proved by the splendid results obtained in the treatment of resistant progressive and otherwise hopeless cases.

Artificial pneumothorax decreases the volume of the lung by the injection of controlled amounts of air through a needle introduced into a free pleural space. It may be relaxing, collapsing or mildly compressive. The more uniform and continuous, the more effective it will be. Refills are necessary at more or less regular intervals over a long period, demanding prolonged cooperation of the patient, which, for economic, business, social, temperamental or other reasons, is too often interrupted or altogether neglected. This leads to intermittence, early loss or complications. To obviate these the injection of oils was introduced.<sup>8</sup> The safe use of oleothorax demands a greater degree of experience and judgment than does the use of simple pneumothorax.

An early, continuous, uniform and moderately relaxing pneumothorax is a prophylactic pneumothorax. It separates the visceral from the parietal pleura, prevents the formation of adhesions, relaxes and rests the lung, is conducive to contraction of early, soft thin-walled cavities and healing of soft exudative or mixed productive pericavitary zones. Massive repeated hemoptysis may be stopped. In bilateral lesions of a similar type, though different intensity, it may be induced on the two sides simultaneously or alternately. An early pneumothorax is not more dangerous to induce or difficult to control than is a later pneumothorax. It may obviate further measures for collapse.

The practice of inducing high degrees of plus pressure in order to secure attenuation of restraining adhesions, desirable as this may seem is neither wise nor safe and frequently causes complications. Obliteration of the pleural space precludes pneumothorax. Adhesions may prevent the induction and maintenance of a satisfactory pneumothorax.

An incomplete pneumothorax, while it may not collapse cavities, does exercise a salubrious effect on the pericavitary lesions. It renders the pleura less sensitive, and the mediastinum more rigid and gives the heart and contralateral lung time to become adjusted to the altered intrathoracic pressure. The patient is thereby fortified

and will better tolerate the necessary more formidable procedures for collapse. These should not be delayed. Prolonged pneumothorax treatment without diminution in the size of the cavities or continuing improvement of the lesions in the lung is not good therapy. It wastes valuable time, courts complications, imperils the final results and withholds from the patient other measures when these give assurance of success.

*Intrapleural Pneumolysis*—Closed intrapleural pneumolysis<sup>9</sup> is the severance of restraining and tethering pleuritic adhesions through a thoracoscope by means of the electrocautery or coagulation.

Pleuritic adhesions are the greatest impediment to successful artificial pneumothorax, once formed they are usually progressive. If restraining adhesions are narrow, like cords or bands, or fan shaped and are long enough to permit the manipulation of the necessary instruments, they may be severed by intrapleural pneumolysis. Thus may an inefficient or partial pneumothorax be made efficient or complete.

A knowledge of the character and content of the adhesions and of their relation to the lung, pericardium and great vessels, especially at the apex, and to the thoracic wall is important, not only because of the effect they may exercise in keeping the cavity open and the lung expanded but also because of the possible danger of puncturing large vessels and the pericardium, and of tearing or eroding the cavity wall or the diseased lung during or subsequent to coagulation.

The number and disposition of adhesions cannot be adequately determined by x-ray study. The thoracoscope is of positive value in the study of intrapleural adhesions.<sup>10</sup> The restraining effect of adhesions must be established before intrapleural severance is attempted.

At the apex of the thorax, the commonest site of resistant adherent cavities, where intrapleural pneumolysis would be most helpful, it is frequently impossible.

Open intrapleural pneumolysis does not require that the operator have training to acquire proficiency in interpretation of adhesions and dexterity in the use of specialized instruments. Open intrapleural pneumolysis is a more difficult and extensive operation. It has a very limited field for broad, short, isolated, tethering adhesions. A satisfactory closure of the pleura is not easy to accomplish.

*Interruption of Phrenic Nerve Conduction*—This paralyzes the diaphragm.<sup>11</sup> It may be made temporary by crushing the main and accessory nerves, which may be repeated to prolong its effect when, after two or three months, the diaphragmatic function returns. Should a permanent paralysis be desired the main and accessory nerves may be cut or 4 or 5 inches of the stem evulsed. Permanent paralysis is occasionally indicated, especially when the lesion has so seriously compromised the lung that a restoration to function is nil. Alexander<sup>12</sup> has proved that repeated temporary interruption is preferable and usually should precede a permanent phrenic interruption. Paralysis of one-half the diaphragm, even if there is no appreciable

elevation, secures a continuous uniform relaxation of the lung. It is more resting than a pneumothorax. The inconvenience of refills, the variable tension and the waning of a pneumothorax are eliminated. Phrenic nerve operations, while simple, have attending dangers, especially evulsion.

The indications are practically those for pneumothorax. Some authorities give interruption of the phrenic nerve preference, especially when continuing cooperation of the patient is doubtful.

Early temporary paralysis of the phrenic nerve will hasten and assure the benefits of general rest in recent thin-walled cavities with a pericavitary zone of the exudative or mixed type. It is positively indicated when a satisfactory pneumothorax cannot be induced, controlled or continued. It may supplement or intensify a unilateral pneumothorax without increasing the pressure. In the case of bilateral lesions it may be performed concomitantly on the worst side. The greatest benefits are in basal lesions. Midfield and infraclavicular lesions are almost equally controlled. A temporary interruption of the phrenic nerve is of advantage to retard reexpansion of the lung on abandonment of the pneumothorax. It is effective in reducing the size of empyema cavities and in relaxing the lung, favoring closure of bronchial fistulas by contracting fibrosis. Massive repeated hemoptysis is controlled by operation on the phrenic nerve. As a palliative procedure in terminal stages to assuage an exhausting cough it is superior to sedatives.

**Scalenectionomy**<sup>13</sup>—In this operation the scalene muscles are resected close to their insertions in the first and second ribs. The unopposed action of these muscles elevating and horizontally rotating the upper ribs is very great. However, when the ribs and intercostal muscles below the third rib are intact the effect of the scalene contraction disseminated over the entire thorax is greatly reduced.

Scalenectionomy does reduce excursions of the upper ribs and rest the apex of the lung, but to a degree so small that its effect on the lesions in the apex is uncertain and often negligible. It is recommended to control the upper part of the thorax as a supplement or sequence to operations on the phrenic nerve. What a successful operation on the phrenic nerve cannot accomplish alone usually requires more than a supplementary scalenectionomy.

**Extrapleural Pneumolysis**<sup>14</sup>—This is the formation of an extrapleural or fascial space overcircumscribing the area of a cavity by finger or blunt dissection through an incision in the periosteal bed of a resected short segment of an overlying rib. The pocket thus formed is filled with some material to maintain firm selective compression of the cavity-bearing area. The compressing effect is immediate. If sputum is abundant overflow, infection is a possibility. Firm fusion of the endothoracic fascia to the ribs, rupture of the cavity or hemorrhage prevents completion of the operation. No satisfactory filling material has been discovered. Gauze<sup>15</sup> has to be replaced, frequently causing considerable pain. Muscle,<sup>16</sup> if sufficient is available, requires a large fenestra for introduction and fixation.

It atrophies and contracts. Air necessitates refill. Bags inflated with water or compressed air<sup>17</sup> leave a projecting tube which is conducive to infection. Paraffin<sup>18</sup> is irritating and heavy and may cause pressure necrosis, erode and perforate the cavity wall or be extruded through the incision. Theoretically ideal, practically it is uncertain. The presence of any foreign material in a wound is a menace. Its use is indicated for the very ill who cannot stand a limited or multiple-stage thoracoplasty and have unilateral or bilateral disease with small to medium sized, chronic, thick walled cavities in a dense fibrotic area with or without severe hemoptysis.

Extrapleural pneumolysis with the use of gauze filling is most efficient in compressing dense residual fibrotic cavities that have failed to close by all other measures. Extrapleural pneumolysis occasionally is useful before a limited thoracoplasty. It is not easier to perform and is scarcely less shocking than a limited thoracoplasty. Though the compressive effect is selective and immediate, the delayed effect is uncertain.

**Thoracoplasty**<sup>19</sup>—The purpose of thoracoplasty is to secure collapse or active compression of a cavity-bearing area in the lung by means of the subperiosteal resection of definite lengths of a variable number of ribs. It may be partial, limited to a few ribs, either the lower or the upper or in stages including as many ribs as may be necessary to obtain adequate compression. The interval between stages is determined by the condition of the patient, time being allowed for the heart and lung to become adjusted to the altered intrathoracic condition and the diseased area in a measure to clear itself. The collapsing effect depends not so much on the length of the ribs resected as it does on the length of the stumps remaining, especially at the posterior aspect, where the resection must be made at the spine and may include the transverse processes. The number of ribs and the length of the segments to be resected are determined by the character, extent and localization of the disease in the lung, the stability of the mediastinum, the thickness of the pleura and the conformation and rigidity of the chest wall. In order to avoid secondary and difficult revision or corrective operations total or subtotal resection of the first to the third or fourth rib should be performed in an upper stage, going well beyond the underlying diseased area of the lung. Whereas short segments and too few ribs may require additional stage, long segments of too many ribs may cause shock, too sudden and great a degree of compression, weakening of an extensive area of the thoracic wall, massive atelectasis seriously embarrassing respiratory and cardiac function, a dangerous degree of autotuberculinization and rapid local or wide dissemination of the disease.

Some excellent authorities, Casper,<sup>20</sup> Semb<sup>21</sup> and Overholt,<sup>22</sup> at the time of thoracoplasty, especially in the upper stage, advocate and perform extensive mobilization of the lung. Casper leaves the wound partially open and firmly packs the area with gauze saturated

with mild silver protein to secure firm compression. Redressing is required for a long time, convalescence is prolonged.

Carl Semb of Oslo, Norway was the first to perform extrafascial apicolysis. He secures a concentric collapse and contraction of the entire cavity-bearing area of the upper part of the lung almost to the level of the hilus. In this operation resection of the upper rib segments is not so extensive as in the total or subtotal type of thoracoplasty. The extrafascial ligamentous attachments and adhesions to the lower cervical nerve roots to the large vessels and to the anterior and posterior mediastinum are carefully severed by sharp and gauze dissection. The entire dome of the pleura is fixed and then depressed. The first three intercostal muscle bundles are double ligated and then severed.

Extrafascial pneumolysis may be performed at the first upper stage or be a step in a revision or corrective operation for collapse of resistant cavities. The latter is more difficult but a safer procedure. With the total or subtotal resection of the upper ribs the collapse of apical and subapical cavities is more efficient and residual cavities are less frequent than in the resection of the limited segments of the former thoracoplasties.

Extrafascial pneumolysis is indicated in the case of apical and subapical cavities with dense fibrotic pericavitary zones without exudative foci.

The manipulation incident to mobilization of the lung and the too sudden and massive compression of an actively diseased lung area are fraught with the danger of a local or widespread dissemination of the tuberculous process. The unsupported mobilized area of the lung beneath the limited deribbed upper portion of the thorax cannot be adequately supported. Paradoxical expansion on coughing of this unsupported lung is inimical to the clearing of the secretion from the diseased area. If the region should contain active foci or exudative areas, manipulation, displacement and active, too sudden massive compression are prone to cause complications. The compressing effect is ideal, the greatest attainable. It is safer to do active forceful compression on a residual cavity in a densely fibrotic area with only low grade if any, tuberculous infection by extrapleural gauze tamponade.

The indications for thoracoplasty are those for collapse therapy in general when lesser measures have failed or the temporary collapsed cavities reopen and quiescent areas become reactivated. The degree of fibrosis and contraction deformity is an index of the rigidity of the mediastinum and the local resistance of the lung tissue. A rigid mediastinum gives assurance of cavity compression and security against mediastinal flutter and displacement.

Contraindications to collapse are fresh, recent exudative lesions in the opposite lung, especially near the base, severe asthma, emphysema, active or decompensated heart disease, uncontrolled diabetes and tuberculosis in other organs are, in proportion to their activity, unfavorable complications. Severe anemia, rapid pulse and low blood pressure are warnings of danger, they prejudice but do not preclude surgical collapse.

Delay in diagnosis has been and is the chief obstacle in the control of pulmonary tuberculosis.

Delay in instituting the proper procedure for collapse compromises and may defeat all efforts to cure.

## Special Article

### THE PHARMACOPEIA AND THE PHYSICIAN

#### THE THERAPY OF DIARRHEA IN CHILDREN

A GRAEME MITCHELL, M.D.

CINCINNATI

*This is one of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee on Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION—Ed.*

For an understanding of the treatment of diarrheal disturbances some consideration must be given to the underlying causes, the pathology and the symptomatology. The seriousness of diarrhea is attested by the fact that approximately 30 per cent or more of all deaths in the first year of life are attributable to gastro-enteric diseases and that even in the second year these still constitute the largest single cause of death.

#### CAUSE OF DIARRHEA

The symptom diarrhea is a common one and a manifestation of a great variety of diseases, some of which are not primarily gastro-enteric. Thus increased peristalsis and increased frequency of intestinal evacuation may occur in most febrile diseases, especially respiratory infections, in toxic or altered metabolic states such as uremia and acidosis in emotional excitement and exposure to high or low external temperature, and in certain types of allergy.

Diarrhea is helpfully eliminative when indigestible material is ingested or irritating chemical products are taken into the gastro-enteric tract or formed in it by bacterial action. Even an excessive intake of food otherwise digestible may cause an eliminative type of diarrhea.

The diarrheal diseases of childhood and especially of early infancy assume special significance because the younger the organism the more pronounced are the consequences of loss of water and electrolytes. An amount of diarrhea which would cause relatively little disturbance in an adult may be of extreme seriousness in an infant. Age is also a predisposing factor in diarrheal diseases, since these are more frequent in early life. Among predisposing causes the effects of high temperature and perhaps also of humidity are important. Diet is a definite factor and, even when the most improved methods of artificial feeding are employed, the breast-fed infant still retains an advantage in respect to the incidence of diarrheal disturbances.

In infancy and childhood it is the condition known as gastro-enteritis that is of greatest significance in causing diarrhea. This term, although the one most widely employed, is not entirely satisfactory, since inflammatory reaction in the gastro-enteric tract may be minor in character. Other designations, however, are little better or are limited in application. The term "summer diarrhea" details the time of most frequent occurrence and the chief symptom, the term "cholera

infantum" denotes that in certain cases there is a profuse, watery diarrhea which resembles Asiatic cholera, the term "ileocolitis" is applicable when there is actual pathologic change in the gastro-enteric tract, and the term "alimentary intoxication" suggests that there are toxic symptoms which are of intestinal origin.

The cause of gastro-enteritis and its accompanying diarrhea is not always obvious. There is no doubt that many cases are due to infection (infectious diarrhea), the organism responsible being frequently the dysentery bacillus. Streptococci are less commonly operative, sometimes causing epidemics of diarrheal disturbance both in children and in adults. Not so clearly established as direct infectious agents, but occasionally the probable cause of gastro-enteric irritation and inflammation, are staphylococci, *Bacillus pyocyaneus*, the gas bacillus and Morgan's bacillus, and it would appear possible that the colon bacillus may at times take on pathogenic properties. Whether the various organisms last mentioned are primarily causative or only secondary invaders after an initial irritation of the gastro-enteric tract, is open to question. That typhoid and paratyphoid bacilli may cause diarrhea even in young infants should always be borne in mind.

Overemphasized in diarrheal disease is the role of parenteral infection, that is, of infection elsewhere than in the gastro-enteric tract. As already stated, diarrhea is part of the symptomatology of acute febrile diseases, especially of the respiratory tract. However, to attribute all acute, severe diarrheal disturbances in infants to such a source is not correct.<sup>1</sup> While there should always be alertness to determine the presence of parenteral infections and to search for otitis media or mastoid infection, it does not follow, as some clinicians have maintained, that every infant who has diarrhea and evidence of acute middle ear disease should have his mastoid cells surgically drained.

#### THE PATHOLOGY OF DIARRHEA

In the instances caused by the dysentery bacillus and other organisms which actually attack the gastro-enteric mucous membrane, there result inflammatory changes and often ulcerative lesions. Peyer's patches and the solitary lymph follicles are prominent and congested. In other cases, as already pointed out, the changes in the gastro-enteric mucous membrane are so slight as not to be noticeable grossly, and only minor inflammatory or degenerative changes are found microscopically. Toxic changes may be seen at necropsy in the liver, kidney, mesenteric nodes and other tissues.

#### THE ASSOCIATED SYMPTOMS OF DIARRHEA

The clinician cannot always accept the history that diarrhea exists. Parents may have different conceptions of the average or normal number of stools. It is not only the number of intestinal evacuations which is important, the physician must himself determine by inspection and examination the water content and the presence of undigested material, blood, pus and mucus. He must decide also when diarrhea becomes more than merely eliminative and helpful in ridding the gastro-enteric tract of irritating or undigested material and when, therefore, it is necessary to make the attempt to check it.

When diarrhea is excessive and continued there may occur anhydremia or lack of sufficient water in the blood, and also dehydration or desiccation of body tis-

sues. The acid-base balance of the body may be disturbed and an acidosis result from loss of base, sodium and potassium, and also because the impaired circulation and the anoxemia of tissues lead to an accumulation of lactic acid. Furthermore because of the sluggish circulation and failure or diminution of blood flow through the kidneys there may come about faulty elimination of acid phosphates and other acids and their accumulation in the body, thus adding to the acidosis. In gastro-enteric disturbances it may rarely happen that vomiting is sufficiently severe to cause such loss of hydrochloric acid that alkalosis eventuates.

#### TREATMENT OF DIARRHEA

It is on a background such as that outlined that the physician must determine his prophylactic and curative treatment of the symptom diarrhea. Breast feeding should be urged for the first several months of life. A period of excessively high environmental temperature may require a temporary diminution of food intake and also an increase of fluid intake to compensate for increased loss of water through the skin. If indigestible food is being administered, this must be stopped. In any febrile disturbance a lowered food intake and an increased fluid intake are indicated. The underlying cause for any diarrheal disturbance should if possible always be determined and eliminated. If a parenteral infection or a toxic disturbance exists, it should be appropriately treated.

Ridding the intestinal tract of irritating material may be indicated at the beginning of a gastro-enteric upset, and especially when fever is present. Fever cannot be employed later as the criterion since it may be due to dehydration. Colonic flushing with salt or soda solution may help in accomplishing this, but the administration of a cathartic is often proper. Castor oil (*oleum ricini*) is a favorite for this purpose—a drachm (4 cc) for an infant or 2 drachms (8 cc) for an older child. A saline cathartic such as milk of magnesia (*magnesia* *magnesiae*) from 2 to 4 or more drachms (8 to 16 cc.) or citrate of magnesia (*liquor magnesi citratis*) from 2 to 4 or more ounces (60 to 120 cc.), or perhaps magnesium sulfate (*magnesi sulfas*) or some effervescent saline may be given to older children. Calomel (*hydrargyri chloridum mite*) is a drug seldom used or indicated in infants or children suffering from diarrheal diseases. However, purgation is no more to be recommended as a routine measure in the treatment of diarrhea than is digitalis to be given to every patient who has a cardiac murmur. If the patient is seen after diarrhea has already rid the intestinal tract of irritating material, and dehydration is present, purgation only exaggerates the symptoms. At this stage, every effort must be made to stop the loss of fluid from the gastro-enteric tract. Certain drugs may be of value in this respect, particularly bismuth subcarbonate (*bismuthi subcarbonas*), which should be given in doses of from 2 to 3 or more drachms (7 to 10.5 Gm.) a day. Bismuth has an astringent and, by its coating of the intestinal tract, a protective action. A common prescription is one containing about 15 grains (1 Gm.) of bismuth subcarbonate to the drachm (4 cc) of chalk mixture (*mistura cretae*), this suspension being given every hour or two after it has been vigorously shaken. The bismuth subnitrate is seldom ordered, since it is liable to be contaminated with lead, arsenic or antimony.

<sup>1</sup> Mitchell, A. G., McCarthy, M. F., Leichter, J. W. and Seinsheimer, Frank. Otitis Media and Its Relation to Gastro-Enteritis. *J. A. M. A.* 92: 970-974 (March 23) 1929.

and because nitrates may be formed from the nitrate and poisoning thus result. Some physicians prefer milk of bismuth (magma bismuthi) in doses of 1 drachm (4 cc) several times a day, and others prescribe bismuth subgallate or subsalicylate because of their astringent properties, given in the same doses as the subcarbonate. There are also a number of proprietary preparations of bismuth. Kaolin (aluminum silicate) or fuller's earth may be used in place of bismuth. A question might be raised concerning their value,<sup>3</sup> they are being mentioned for the sake of completeness and without recommendation. They may be given in doses of 15 grains (1 Gm) every few hours so that 2 or 3 or more drachms (7 to 10.5 Gm) is taken a day. Activated charcoal (carbo activatus) may be prescribed in place of kaolin, given in the same doses.

In the more subacute stages of diarrhea, astringent preparations containing tannic acid are occasionally administered but apparently have little effect. Tannic acid may be given as tannalbum (albumini tannas) in doses of from 10 to 30 grains (0.65 to 2 Gm) three or four times a day. In more chronic diarrheas there are occasionally employed, but not to be recommended, such drugs as lead acetate, copper sulfate and silver nitrate. These are all poisons and have little if any good effect.

Opium in some form and in doses consistent with the age may be ordered for pain and restlessness. It is usually stated that it decreases peristalsis by its effect in increasing the tone of the intestine, although there is some question concerning its mode of action. A common manner of administering opium is as paregoric (tinctura opii camphorata) in doses of from 15 drops to 1 drachm (1 to 4 cc) several times a day, depending on the patient's age.

It is generally admitted that so-called intestinal antiseptics or disinfectants are without value, although occasionally salol (phenylis salicylas) in doses of from 2 to 5 grains (0.13 to 0.33 Gm) three times a day is still ordered.

Space does not permit a lengthy discussion of the dietary treatment of diarrheal diseases. The principles usually followed are initial starvation, only such solutions as barley water or 5 per cent dextrose solution being given for a period of about twenty-four hours if the patient's condition permits and if he is seen early in the diarrheal disturbance. Later there is the institution of a limited intake of food until the diarrhea improves. Some pediatricians advise starvation from milk for at least several days. Usually, however, a low fat and low carbohydrate and a high protein milk mixture such as skimmed milk or various preparations of protein milk are indicated. Lactic acid milks, particularly those produced by fermentation with lactic acid organisms and still containing them in viable form, are thought to be efficacious by many physicians. The apple diet, recommended by Moro<sup>4</sup> and others, or pectin-agar mixtures evolved by Winters and Tompkins,<sup>5</sup> seem to be helpful in many cases. In older children milk in any form may be prohibited for several days and the diet consist of thick cereal gruels, toast, fruit juices, albumin water and broths.

Most important is the administration of fluid. Water or physiologic solution of sodium chloride (0.85 per

cent sodium chloride solution, liquor sodii chloridi physiologicus) or 5 per cent dextrose solution should be given freely, but in small amounts if vomiting is excited. Diarrhea does not allow fluid to be retained by rectum. Often the need for fluid is so urgent that it must be administered by such parenteral routes as subcutaneous or intravenous injection. This presentation does not permit detailed discussion of fluid therapy, but several remarks are indicated. 1 The fluid given may be physiologic solution of sodium chloride or 5 per cent dextrose (d-glucose) solution, or a mixture of equal parts of the saline and 10 per cent dextrose solution so that the resulting strength of dextrose is 5 per cent. Other acceptable solutions are Ringer's solution, Hartmann's solution<sup>6</sup> (dispensed in ampules) and Darrow's solution.<sup>7</sup> 2 Physiologic solution of sodium chloride and dextrose solution may be given subcutaneously, the other solutions intravenously. 3 The continuous intravenous drip is a satisfactory method of administering fluid, from 15 to 20 drops a minute being allowed to flow into the vein.<sup>8</sup> 4 The total amount of fluid taken by any route (orally, subcutaneously or intravenously) should be known so that no edema will be caused; the normal fluid requirement of approximately  $2\frac{1}{2}$  ounces of fluid per pound daily in the first six months of life being remembered in order that the individual infant's need in the emergency of dehydration can be estimated and more than this given at first when indications exist.

**Acidosis**—Mention must be made of the treatment of acidosis in acute diarrheal disease. While this is a secondary manifestation, brought about by the mechanism already discussed, the combating of it may be life saving. Usually it follows only after marked loss of water, and the first defense against it is, in fact, the administration of sufficient fluid. The presence of acidosis can be determined with certainty only by a determination of the carbon dioxide content of the blood, since clinical symptoms are not always diagnostic, the most characteristic one, hyperpnea, occurring also in alkalosis. It is a mistake to administer sodium bicarbonate in large doses to every sick infant or child, since alkalosis may thus be brought about. In one year in the Children's Hospital of Cincinnati there were admitted four infants, all of whom died, who had severe alkalosis because of excessive administration of alkali. If a physician responsible for the care of an acutely sick infant suffering from gastro-enteritis is not in a position to determine the carbon dioxide content of the blood, the patient should be sent to a hospital where this can be done, the high mortality of gastro-enteritis in infants demanding this. Furthermore, it must be emphasized that acidosis may recur several times and require frequent treatment. It should be noted that Hartmann's solution, an excellent one for the administration of fluid, does not contain sufficient sodium lactate for the treatment of severe acidosis. In fact he recommends for this the more concentrated "one-sixth molar lactate." Cullen<sup>2</sup> has evolved a formula for the administration of sodium bicarbonate in acidosis which is as follows:  $g = b \times \text{wt (Kg)} \times 0.026$ . Sixty-five is considered the normal value of carbon dioxide in

5 Winters Matthew and Tompkins C A. Pectin-Agar Preparation for Treatment of Diarrhea of Infants. *Am J Dis Child* 52: 259-265 (Aug) 1936.

volumes per cent. In this,  $g$  = sodium bicarbonate needed in grams,  $b$  = deficit ( $65$  — determined carbon dioxide content in volume per cent), i. e., 1 Gm. of sodium carbonate per kilogram of weight raises the carbon dioxide content about 40 volumes per cent.

For example a patient weighs 10 Kg. and his blood carbon dioxide content is 15 volumes per cent. It is desired to raise his blood carbon dioxide content to 65.  $b = 50$  ( $65 - 15$ ).  $50 \times 10 \times 0.026 = 13$  (Gm. of sodium bicarbonate to be administered which should be given in 5 per cent solution i. e. 260 cc. of a 5 per cent solution of sodium bicarbonate).

As a matter of fact it is not necessary to attempt to reach the normal limit of 65 volumes per cent of carbon dioxide content. The carbon dioxide content of 50 would bring the child well out of the danger zone. Therefore the calculation could be ( $50 - 15$ ) or  $35 = b$  (or deficit).  $35 \times 10 \times 0.026 = 9$  (Gm. or 180 cc. of a 5 per cent solution of sodium bicarbonate). Seven per cent solution of sodium bicarbonate may be used if the amount of fluid injected needs to be reduced.

In emergencies when analyses of the carbon dioxide content of the blood are not possible coma or impending coma may be used in an indication for alkali therapy, and usually hyperpnea and convulsions likewise although, as stated, hyperpnea (and also convulsions) may occasionally be present in acute alkalosis. Under any conditions the administration of alkalis should be stopped when the urine becomes pink to phenolphthalein indicator (above pH 7). In normal infants from 30 to 45 grains (2 to 3 Gm.) and in older children from 60 to 75 grains (4 to 5 Gm.) of sodium bicarbonate will render the urine alkaline but in acidosis from four to ten times as much may be required. One disadvantage of the administration of sodium bicarbonate by mouth is the fact that it may increase the diarrhea.

In the treatment of acute diarrheal disease in infants repeated small transfusions may be indicated. If continuous intravenous drip is being employed, blood may be administered through the same apparatus.

If convulsions occur calcium gluconate may be given intramuscularly or intravenously in doses of from 5 to 10 cc. of a 10 per cent solution, and perhaps also sedatives of the barbitol group may be administered. Minot<sup>9</sup> has found guanidine-like substances in the blood in gastro-enteritis in infants and children and also suggests the administration of a calcium compound, since in guanidine intoxication the calcium ion concentration of the blood is lowered, a condition which would predispose to convulsions.

**Dysentery Infection**—In dysentery infection there must, in addition to the measures already outlined, be considered the administration of antidysentery serum. It may be stated that, at least in infants and children, this has no demonstrable value. Sodium thiocyanate has been suggested as a possible prophylactic and curative agent in doses of one-third grain (0.022 Gm.) per kilogram of body weight daily.<sup>10</sup> In diarrhea due to amebic infestation several drugs have been recommended, such as carbarsone, about  $3\frac{1}{2}$  to 4 grains (0.25 Gm.) twice a day for ten days,<sup>11</sup> chinofon powder

(mixture of 7-iodo-8-hydroxyquinoline 5 sulfonic acid sodium bicarbonate and sodium iodohydroxyquinoline sulfonate from 15 to 45 grams (1 to 3 Gm.) a day until about 600 grams (40 Gm.) has been given<sup>12</sup> or iodoform (iodochlorohydroxyquinoline), 230 grains (15 Gm.) given orally in two courses of about 12 grains a day (0.75 Gm.) for ten days with a week's rest period between.<sup>13</sup> Emetine hydrochloride also appears to be a specific antamebic drug, the adult dose being from one-third to 1 gram (0.22 to 0.65 Gm.) hypodermically daily (or better not more than 10 mg. per kilogram daily) for a period of eight days.<sup>14</sup> Enemas of 1:5000 solution of quinine may also be given in amebic dysentery.

**Chronic Diarrhea**—In chronic diarrhea there is almost invariably a pathologic background of ileocolitis. A search must always be made to determine any micro-organisms which might be causative. Thus there may be discovered the dysentery bacillus or in some cases, ameba. Bugen<sup>1</sup> believes in the etiologic importance of a specific form of diplostreptococcus. In chronic amebic infestation the measures and drugs already discussed may be tried. Bugen has claimed success in treatment with bacterial antigens prepared from the organism he described, but others have not always seen much benefit from this. In fact many chronic cases of ileocolitis must be classed as idiopathic or nonspecific, since no particular organism appears to be responsible. Vaccines made from organisms such as streptococci or colon bacilli are not of much value. In chronic ileocolitis operations such as appendicostomy or ileosigmoidostomy are sometimes recommended and the fecal stream in the latter operation may be left short circuited for months or years.

The drug treatment of chronic diarrhea cannot be said to be very satisfactory. The astringent remedies such as bismuth or tannic acid already mentioned, may be tried. It is claimed that calcium gluconate or lactate has an effect on healing the intestinal ulceration, and solution of parathyroid (liquid parathyroid) has also been employed.<sup>15</sup>

Examples may be given of the therapy to be employed in the usual case of gastro-enteritis.

**Mild Gastro-Enteritis Without Vomiting, in an Infant Aged 6 Months**—The first day nothing by mouth for twenty-four hours except water, 5 per cent dextrose solution or physiologic solution of sodium chloride, which should be offered in amounts of 3 ounces every three hours, but without forcing. Hypodermoclysis of 200 cc. or more of physiologic solution of sodium chloride or 5 per cent dextrose solution is given twice a day.

The second day, if there is some improvement, half strength skimmed milk, skimmed lactic acid milk or protein milk about 3 ounces every three hours, with 5 per cent dextrose offered between feedings. Hypodermoclysis is given if necessary.

The third day, if improvement continues, full strength skimmed milk is given.

After several days the formula is slowly increased to full strength. Sugar may be added to the formula on the fourth or fifth day, orange juice and cod liver oil being added at approximately the same time.

Severe Gastro-Enteritis and Marked Dehydration with Some Vomiting, in an Infant Aged 6 Months. In addition to the treatment outlined for a mild case the following procedures are suggested.

Five per cent dextrose in physiologic solution of sodium chloride given intravenously. Other balanced salt solutions may be used.

Transfusions given after the anhydremia has been partially corrected.

The total fluid in the twenty-four hours to be approximately 3 ounces (100 cc) per pound of body weight.

Fluids by mouth limited to from one-half ounce (15 cc) to 1 ounce (30 cc) of 5 per cent dextrose every three hours.

Determination of the carbon dioxide content of the blood and correction of acid-base balance if necessary.

In severe cases frequent determinations of the carbon dioxide content of the blood. Calcium gluconate from 5 to 10 cc of 10 per cent solution intravenously if there are convulsions.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER, Secretary

### BRISTOW ULTRAVIOLET LAMP ACCEPTABLE

Manufacturer: Bristow and Company, 2861 West Pico Boulevard, Los Angeles.

This lamp generates ultraviolet radiation of the mercury glow low pressure type for use in physicians' offices and in hospitals or clinics. Both a hexagonal grid and an official applicator combination are available. It is a semiportable unit on a stand with three legs and ball bearing casters. The bakelite parts such as hood, transformer and official cases may be procured in ebony, walnut or old ivory finish, while the stand and trimmings are chrome plated. The unit weighs approximately 42 pounds.

Bristow Ultraviolet  
Lamp

The grid of 8 mm quartz tubing is coiled in a flat spiral (hexagonal pattern) and has an exposed length of 183 cm (6 feet). The grid is attached to an aluminum reflector with specially treated gray finish. This is packed by a double reflector case of dome shape, a bakelite back and an aluminum shell. A handle on the outer shell permits closer applications. The outside diameter of the reflector is 36 cm (14 inches).

Tests were submitted by the firm concerning the spectral distribution and quantity of ultraviolet radiation produced by the lamp. A Hilger Quartz Spectrograph indicated a characteristic cold quartz mercury vapor spectrum. Energy observations taken with a Burt Ultraviolet Photometer calibrated against standards prepared by the Bureau of Standards showed a spectral energy distribution of 89 per cent between 2,000 and 2,600 angstroms, 10 per cent between 2,600 and 3,000 angstroms and 1 per cent between 3,000 and 3,200 angstroms.

Power consumption was 80 watts at the beginning and end of a three hour run.

Since the Council bases its acceptance of lamps on the erythemic test as well as spectral distribution and intensity of radiation, the firm submitted these data. The intensity of ultraviolet radiation for therapeutic purposes produced by the Bristow

lamp at 4 inches was 4,800 microwatts per square centimeter and at 24 inches was 640 microwatts per square centimeter. At the latter distance, a minimum perceptible erythema may be produced by an exposure of about one minute.

The unit was examined by a qualified investigator and found to give satisfactory service. However, because of the high intensity of radiation of wavelengths shorter than 2,800 angstroms (amounting to about 90 per cent of the total) this lamp is not acceptable as a sun lamp for home use but is acceptable as a therapeutic lamp for professional use in the office or in the home if under the supervision of a physician.

In view of the foregoing report, the Council voted to accept the Bristow Ultraviolet Lamp for inclusion in its list of accepted apparatus.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING PARAGRAPH HAS BEEN ADOPTED BY THE COUNCIL AS AN ADDITION TO THE STATEMENT ON TRICHLOROETHYLENE NOW APPEARING IN NEW AND NONOFFICIAL REMEDIES.

PAUL NICHOLAS LEECH, Secretary

**TRICHLOROETHYLENE** (See New and Nonofficial Remedies, 1938, p. 54).

*Actions and Uses* (For first paragraph see New and Nonofficial Remedies, 1938, p. 54).

Trichloroethylene has recently been proposed for use in the prevention and treatment of attacks of angina pectoris. It is believed that trichloroethylene is worthy of trial for this purpose, provided patients are under continued medical supervision, as in the clinic. Trichloroethylene is a general anesthetic, and its use for this purpose is subject to all the dangers and disadvantages of anesthetics. It should never be prescribed in bulk or taken in large doses. From 1 to 3 cc a day, in divided doses, is ample. The drug should always be taken with the patient in a reclining position, and the material should not be substituted for amyl nitrite in the treatment of the acute anginal attack. Each patient should be warned of the possibility of addiction. Excessive dosage of trichloroethylene may mask a severe attack of coronary pain and lead to its being ignored where it should receive immediate medical attention, together with bed rest. It should be used cautiously in the prevention of attacks because it may mask pain which otherwise would indicate exertion beyond the capacity of the heart.

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

**SULFANILAMIDE** (See New and Nonofficial Remedies, 1938, p. 450).

**Sulfanilamide-Maltbie**—A brand of sulfanilamide-N N R. Manufactured by the Maltbie Chemical Co., Newark, N. J. No U. S. patent or trademark.  
*Sulfanilamide Tablets* 5 grains.

**STROPHANTHIN** (See New and Nonofficial Remedies, 1938, p. 200).

The following additional dosage form has been accepted.

*Hypodermic Tablets Strophanthin*  $\frac{1}{100}$  grain Upjohn. Physiologically standardized by the Magnus modification of the Hatcher and Brody method to contain approximately 1.5 cat units.  
Prepared by The Upjohn Company, Kalamazoo, Mich. No U. S. patent or trademark.

**PYRAMIDON** (See New and Nonofficial Remedies, 1938, p. 362).

The following additional dosage form has been accepted.  
*Pyramidon Tablets* 2 grains.

**SOLUTION OF POSTERIOR PITUITARY** (See New and Nonofficial Remedies, 1938, p. 350).

**SOLUTION PITUITARY EXTRACT U S P (UPJOHN)**—A brand of solution of posterior pituitary-U S P.

Manufactured by The Upjohn Company, Kalamazoo, Mich.  
*Ampoules Solution Pituitary Extract U S P (Upjohn)*  $\frac{1}{2}$  cc.  
*Ampoules Solution Pituitary Extract U S P (Upjohn)* 1 cc.

SATURDAY, JANUARY 14, 1939

## SUBSCRIPTION AND FELLOWSHIP DUES FOR 1939

The colored slip found in this issue of THE JOURNAL the customary reminder to Fellows and subscribers that dues for 1939 are now payable. While many Fellows and subscribers have already sent their remittances for 1939, the reminder this week will be a convenience to those who have not paid. The slip is cut to form a return envelop when folded, and postage is not required. It will be recalled that several months ago the Board of Trustees of the Association found it necessary to change the subscription and Fellowship dues from \$7 to \$8 annually because of the increasing demands made on the Association. Operating costs, labor costs and prices of materials have increased. Whereas the Association previously was not liable for payment of Social Security taxes, the ruling has been reversed and, unless set aside, will call for an expenditure of approximately \$100,000 in the near future. In addition the suit instituted by the Department of Justice of the federal government will involve another item of unpredictable expense if the Association is to defend itself properly. The spirit in which thousands of Fellows and subscribers have already paid the new rate is most gratifying—in fact, numerous letters have been received from physicians expressing willingness to make outright financial contributions to the Association, if requested. Fortunately such contributions are not necessary at present, but in the interest of good business procedure it is hoped that all those whose dues for 1939 are not yet paid will use the colored slip in this issue of THE JOURNAL and remit without undue delay. This will obviate a considerable amount of clerical expense and the sending of personal statements

## INCIDENCE AND FUTURE EXPECTANCY OF MENTAL DISEASE

Not only the present incidence of mental disease is a problem of major proportions but also that occasioned by the future expectancy of this condition. Modern civilization has led to an increasing urbanization of the population. The belief is prevalent that there has been an alarming increase in mental disease in recent years and that this increase is in a measure attributable to the stress and strain of urban environment.

Dorn<sup>1</sup> points out that the problem of measurement of the incidence of mental disease is complex, since there is no sharp line of demarcation between normality and abnormality. Even though there is a definite physical basis for many mental disorders, mental disease is fundamentally a cultural concept which varies with different groups. Many persons who might merely be considered eccentric in a rural district would be unable to cope with the exigencies of an urban environment and might even be committed to a hospital for mental diseases. It is necessary to measure the occurrence of mental disease by the number of persons with recognized mental disease committed to an institution. This type of measurement is of value although it does not, of course, include all cases of mental illness but merely those which have been recognized as needing institutional care, with subsequent hospitalization. One index frequently used for expressing the incidence of mental disease is the number of first admissions per hundred thousand of population. However, this rate is subject to the same criticism as a crude death rate, it is affected by the composition of the population to which it refers. Since mental disease is more frequent among the elderly than among the young, the rate will be high if the proportion of elderly persons in the population is large.

A simple modification of the method of computing a life table leads to a measure of mental disease analogous to the expectation of life of the life table. In this manner a measure is obtained which may be called the expectation of mental disease or, more accurately, the expectation of commitment to a mental hospital. In order to calculate this, the mortality and first admission rates of a given population at a given time are applied to a particular number of infants, 1,000 for instance, and the number of those who would be alive and sane at each age if they were continually subject to the assumed mortality and disease rates is determined. The expectation of mental disease is then simply the ratio of the number who live to become insane to the original thousand infants. True, a mere increase in hospital facilities results to some degree in an increase in the number of first admissions to mental hospitals. This factor was eliminated as far as possible in Dorn's study by using data from Massachusetts, New York and Illinois, where hospital facilities have been fairly adequate for several years and where the combined population was 24,000,000 in 1930.

The contention that the incidence of mental disorders is rapidly increasing does not receive support from data obtained on commitments to mental hospitals in these states. Analysis of commitments in these areas shows that the number of first admissions per hundred thousand of population decreased among women under 70 years of age in each state. This was true also for men in Massachusetts. In New York and Illinois commitment rates increased somewhat after the ages of 45 or 50, but in younger persons a decrease occurred. The average number of patients in state hospitals rose from 248,852 in 1926 to 347,640 in 1935. An increasing proportion of old persons, increasing urbanization and similar environmental factors may explain this increase. A greater number of persons now live to develop mental disorders owing to an increased expectancy of life. An increase in the proportion of the total population which eventually is afflicted with some mental disturbance may result, even though the probability of the development of mental disease remains unchanged for each age. Present population trends point toward such an increase in the number of persons in the age groups in which mental disease is most frequent. As a consequence the number of persons with mental disease may be expected to increase although there may be no increase in the incidence of the disease.

#### ERYTHEMA NODOSUM

A small epidemic of erythema nodosum of exceptional interest, involving fourteen cases, has been reported recently by Brandon and his colleagues<sup>1</sup> from Canada. The school in which the epidemic occurred was attended by 173 boys from 10 to 19 years of age and was situated on a 300 acre farm with widely spaced buildings. There was a staff of thirty-five persons. The boys slept in five cottages, each with a capacity of forty-two. There was, however, ample opportunity for contact between the boys outside their cottages. Careful epidemiologic, clinical and laboratory observations were made. Tuberculin tests were made on 158 of the 173 boys, 139 of them reacted positively to 1 mg. of tuberculin or less. Light of the cases of erythema nodosum occurred in one cottage, four in another, one in each of two others and none in the fifth cottage. All fourteen of the boys were found to be highly sensitive to tuberculin and twelve showed definite or suggestive lesions of tuberculosis. All the positive tuberculous lesions among the cases of erythema nodosum were of the childhood or hilar gland type. Among the boys without erythema nodosum there were sixteen cases of minimal or suspected tuberculosis. No active or open cases were found in the school, in the staff or in the community, and none of the boys had demonstrable tubercle bacilli in the sputum. However, the evidence that the school population had recently been highly sensitized to tuber-

culin was definite and a boy of 17 with open pulmonary tuberculosis had been removed from the school five weeks after the onset of the epidemic. It was concluded that the source of the epidemic was probably this boy and that the disease was probably transferred by direct contact.

The frequent association of erythema nodosum with tuberculosis has led many students of the subject to the conclusion that erythema nodosum is of tuberculous origin, probably on a sensitization basis. Nevertheless there has been much controversy as to whether it can be considered a nonspecific reaction and to accompany such diseases as rheumatic fever on that basis. Wallgren<sup>2</sup> has in fact expressed the view that erythema nodosum should be regarded as a nonspecific allergic cutaneous eruption which appears especially in tuberculosis but occasionally in other infections and even may possibly be provoked by noninfectious agents. He feels that the epidemics of erythema nodosum which have been described and which form one of the supports of its being an expression of an acute specific infectious disease are given a natural explanation by this view. Elsewhere Wallgren<sup>3</sup> argues on what seems to be sound evidence that there is a true rheumatic erythema nodosum. He cites three cases in detail and mentions six points in favor of this syndrome: (1) the pains in the joints, (2) the endocardiac lesion, established by physical examination, (3) the electrocardiographically demonstrated myocardiac lesion, (4) the protracted, highly increased sedimentation rate, (5) the period of fever in connection with the eruption and (6) the absence of any other demonstrable cause of the erythema nodosum, particularly the absence of tuberculous infection (Mantoux, 10 mg., test made twice with negative results, an interval of six weeks having elapsed between the two tests).

Van Heukelom<sup>4</sup> as well agrees that at present erythema nodosum should be considered a nonspecific allergic (or hyperergic) syndrome which in the majority of instances is due to tuberculosis but may occur also in streptococcal infections and probably other disorders.

Although not an extremely common disease, erythema nodosum possesses an interest and significance beyond its usual apparent frequency or seriousness. As a rule it appears as a syndrome of well established clinical course with a characteristic pathologic picture. It is tempting therefore to consider it a specific disease with definite and constant causation, but, as has already been pointed out, its appearance in the absence of tuberculosis has thrown great doubt on the validity of this assumption. There are other lesions or syndromes of similarly controversial nature, such as the Aschoff body in the heart and the condition commonly called a "cold," the specific natures of which are also not yet definitely

established. Such questions constitute fascinating enigmas for medical research. The solution of these questions is more than an academic problem, since on accurate etiologic diagnosis alone can adequate specific treatment be instituted.

## Current Comment

### COMMENTATORS SPREAD FALSE NEWS

In newspapers throughout the United States on Sunday, January 8, the column written by Drew Pearson and Robert Allen entitled "Washington Merry-Go-Round" contained the following item:

#### MEDICAL SOCIETY VAINLY TRYING TO COMPROMISE WITH U. S.

Since their indictment last month by a Federal Grand Jury on charges of antitrust law violation, officials of the American Medical Society have made overtures to the Justice Department to compromise the case in out of court agreement.

So far, the negotiations have got nowhere because of the physicians' insistence that the Medical Society be given special privileges under the law.

As far as is known in the headquarters office of the American Medical Association, no official of this Association has made overtures to the Justice Department to compromise the case, neither have the attorneys for the Association, nor has any official been authorized to make overtures or to conduct such negotiations. A telegram was sent to Messrs. Pearson and Allen calling attention to the misstatements of fact. No answer was received. Mr. Allen was then called on the telephone. He said: "We received our information from the Department of Justice from a source we consider unimpeachable."

### CANCER RESEARCH

A distinguished committee<sup>1</sup> appointed by Surgeon General Thomas Parran has listed as the three most important lines of fundamental investigation on the cancer problem (1) study of the transplantable tumors, which has yielded information on the biology of the malignant cell, (2) the conditions governing the experimental induction of malignant tumors and (3) the part played by genetic factors in the development of cancer. The first has yielded information indicating that malignancy is the result of a fundamental change in cell physiology. The general conclusions which should be derived from extensive studies of the identification of malignant tumors have been that so-called carcinogenic agents start a process which appears to lead to malignancy but once the malignancy starts the agents apparently play no further part in the picture. Almost all, if not all, classes of cells may be rendered malignant by one or more agents. The expectation that with this method of inducing tumors it would be possible to trace the transformation of normal cells into malignant cells has not yet been realized. Much has also been already gleaned from studies of hereditary factors in malignancy, especially in experimental animals. There are, the report states, two distinct objectives in further

research: first the causal genesis of tumors, including the inciting causes, and second the formal genesis or the factors responsible for the nature of the cancer cell and its tendency for unlimited multiplication. Somewhere, it is felt, between the inherited or acquired cell tendency and the factor which releases this tendency lies the crux of the cancer problem as far as the inception of the disease is concerned. Further, it is pointed out that investigation of the characteristics of the cancer cell belongs in the field of cell physiology, and the understanding of the process must be dependent on advances in the understanding of the growth and differences of normal cells. This field requires definite nurturing and it is felt that an important function will be served if this line of investigation is stressed.

### "GROWING PAINS" IN CHILDREN

The so-called growing pains in children have been variously interpreted as a normal phenomenon or as a manifestation of rheumatic fever. Recently Hawksley<sup>1</sup> reported an analysis of 115 cases of growing pains based on an examination of 1,000 children seen in London and Birmingham. Sixty-four of these 115 were subjected to follow-up examinations four years after the initial examination. Although no definitely associated diseases were discovered, there was commonly a history of frequent colds and coughs with coincident exacerbation of pains, signs of general but vague ill health, rather frequent minor orthopedic deformities, some fibrositis in certain cases and psychologic maladjustment. In conjunction with the 189 cases followed up by Sheldon and the sixty-four here reported, cardiac rheumatism was revealed to have developed in less than 0.8 per cent. Hawksley concluded that the syndrome of growing pains is not related to rheumatic fever or subacute rheumatism and does not provoke rheumatic carditis. The pains may be associated with a number of conditions which can usually be discovered and treated by ordinary clinical methods. This work finds substantial agreement with a similar study reported by Shapiro<sup>2</sup> at the June meeting of the American Rheumatism Association. Shapiro made a follow-up study at the Lymanhuist heart clinic of 200 children who complained only of leg pains. The pain characteristically comes on at the end of the day and often awakens the patients during the night. Laboratory studies give normal results. None of Shapiro's patients developed rheumatic heart disease. He concluded therefore that this syndrome, which is so common during healthy school childhood and adolescence, is due to normal growth and clearly not to rheumatic fever. The discussion following this paper indicated general accord on the nonrheumatic nature of most so-called growing pains. In the light of these more recent observations, great skepticism should be attached to a diagnosis of rheumatic fever in those children whose only symptoms consist in vague muscular pains and aches in the lower extremities.

# ORGANIZATION SECTION

## AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

### Harris County, Texas

The Harris County Medical Society of Texas returned a very complete summary of its study of the need and supply of medical care in its county. Harris County has a population of 425,000 of which the Houston District contains the greatest proportion, about 340,000. The thoroughness with which the county medical society carried out this study is verified by the number of returns they obtained as indicated in table 1.

It is significant to note that the welfare and relief agencies, the health departments, the nurses' organization, the hospitals, the schools and the other organizations which arrange for or provide medical care are practically 100 per cent represented, while the percentage of physicians, dentists and pharmacists who returned reports is considerably less.

Table 2 is a summary of the figures reported by the ten hospitals.

During 1937 the hospitals cared for 22,186 pay or part-pay patients, 11,159 public charges and 10,712 free patients. Seven of the hospitals maintain outpatient departments and treated 101,593 patients in those departments during the year. A total of 1,331 persons needed medical care but were not admitted as bed patients because they were indigents and were referred to the City-County Hospital or because they were not residents of the county and therefore were ineligible for county aid. The tuberculosis hospital reported failure to provide care for some because of lack of beds. Some persons were turned away because they failed to keep their appointments.

In determining a person's ability to pay for hospitalization, the hospital personnel based their decision on the person's income after expenses for necessities—food, rent and clothing—had been deducted.

In the hospital outpatient departments 101,593 patients were treated. These patients made 118,397

visits, free medicine was provided by pharmacists in 2,013 cases, and they compounded 5,207 prescriptions at cost or reduced fees during 1937.

The 266 physicians included in the study reported that they had given free service to 22,725 persons in their offices, in the homes or hospitals and had devoted 27,971 hours to free patients in clinics. The thirty-four dentists provided 994 persons with free care in their offices and gave 960 hours of free service in clinics.

To check the figures returned by the physicians and dentists a check form was sent out on which the physi-

cians, hospitals, individuals and various organizations to determine the economic status of these persons and their need for assistance in obtaining medical care and hospitalization. Persons eligible for relief and emergency cases in need of hospitalization are taken to the City-County Hospital. During the year the welfare and relief agencies reported that they had been unable to provide medical care to seventy persons who needed such care. They stated that the reason for this was that in most cases the persons were not residents of the county and therefore were ineligible to receive county aid.

The nurses' organization, with twenty-two full-time public health and visiting nurses, reported visiting 2,354 persons in 1937 who were not receiving medical care. Of this number seventy-eight were unable to obtain medical services. The reasons for this inability were the distance to any source of medical care and lack of funds to pay for medical services, in some cases the persons were transients who had no funds to pay for such services. The nurses stated that they had provided care to all persons who had requested their services.

The health department had no requests for medical services that could not be provided, and they knew of no person in need of medical care who was not receiving such care.

The elementary and secondary schools, which provide physical examinations, reported that 14,992 of the pupils needed some medical care but that only twenty of these were not provided with the needed care, and that was due to their parents' negligence or procrastination.

The physicians and dentists listed eight instances in which medical or dental care was not given to persons

TABLE 2—Information Obtained from Hospitals

needing or requiring such services Their reasons were summarized as follows

- 1 Personal differences between patient and doctor
- 2 No bed available
- 3 No funds
- 4 No reason given

For the whole area, 2,196 persons were unable to obtain either medical, dental or hospital care The one reason for failure to provide this care given by the organizations reporting the majority of these cases was that the persons were transients and ineligible for county aid

With regard to preventive medicine, 110 physicians perform preventive services in private practice, four in the health departments and thirty-six for other agencies All children who entered school for the first time in 1937 were successfully vaccinated against smallpox For each 1,000 children born alive 200 were immunized against diphtheria One per cent of the births were not attended by a physician or midwife Of the total

#### ARRANGEMENTS FOR LOW INCOME AND INDIGENT PATIENTS

What plans, understanding or arrangements exist by which the county medical society and other organizations undertake to provide or arrange for medical services for those who need and are unable to pay for such services?

##### Nurses' Organization—None

**Health Departments**—There is a liaison committee of the Harris County Medical Society Through this committee and the board of health the plans are working out agreeably between the county medical association and the city health department

**Welfare and Relief Agencies**—1 There is no formal arrangement I would like to have one I would like to discuss the subject of fees so that we would be operating our clinic in complete agreement with the feeling of the medical society about fees and other matters Many of our cases are not medical ones Many of the children are not medical cases Many of them are examined only by our psychologist In many cases a social worker does most of the work

2 Adequate care is given by the local hospitals and private physicians and dentists

3 All patients who are not violently insane and who are cooperative that need general hospital care are sent to Jefferson Davis Hospital

4 We have the fullest cooperation of the doctors and social workers connected with our charity hospitals

5 A representative of the medical society is appointed to serve on our agency board

6 We have been very much pleased with the cooperation given us by the hospitals, clinics and doctors in private practice

7 We refer patients needing hospitalization to either Hermann or Jefferson Davis Hospital

8 No definite policy has been established but satisfactory cooperation exists between the hospitals and this agency

9 The clinics giving medical attention outside the scope of our free antituberculosis clinic have for years given prompt attention to cases sent them by us The Houston Tuberculosis Hospital patients are all passed on by the Houston Anti-Tuberculosis League, which acts as a "clearing house" for admission of patients to this institution

10 Florence Crittenton Home receives excellent cooperation from Jefferson Davis Hospital, Hermann Hospital, the city health laboratories, who make laboratory tests for this agency, Texas Dental College, Junior League Clinic, Mexican Clinic, TB Clinic, Maternal Health Center and the Public Health Nursing Association We pay Methodist Hospital a nominal fee for the delivery of the patients in our institution

11 Examination of school children is taken care of by the regular school medical staff The Harris County Medical Society also has a centralizing liaison committee which arranges and provides for examination of preschool children who cannot afford a private doctor

**Colleges and Universities**—1 Physicians and dentists assist in health examinations and health advice

2 Medical and dental members of the college staff provide medical and dental services on a low income basis for students who require services on this basis

**Pharmacists**—1 The local medical society contributes its services to the two charity hospitals—which takes care of the needy in this locality

2 The physicians who are members of the Harris County Medical Society contribute their service to patients who are unable to pay—also service on the staff of the City County Hospital

3 Have always been able to find a doctor more than glad to take care of a worthy case

4 It is taken for granted that a physician will make a call (and not one has ever refused) when an emergency exists and the patient has no money and no income When the emergency is relieved, the patient is either continued to be treated free of charge by the physician or is sent to the City-County Hospital

**Secretary**—The Medical and Dental Service Bureau, owned and operated by the members of the Harris County Medical Society, undertakes to finance medical, dental and hospital service for any one who does not wish to apply to a clinic or charity hospital

#### COMMENTS

The number of comments which accompanied this study is so great that it is not possible to publish them all A summarization representative of each group is given

**Physicians**—The number of free clinics, governmental hospitals and philanthropic organizations which provide medical care offer every one an opportunity to obtain medical care This abundance of free services available tended to create malingering by people who could well afford to pay for medical services The amount of free services performed by the physicians has already been given

**Dentists**—The majority of the people could obtain and pay for all necessary dental services if they made a sincere effort to make arrangements for obtaining the services The indigent are provided for in the free clinics and by the relief agencies The people in the low income groups can secure good dental services at rates within their ability to pay just as easily as they obtain any other services or goods they really desire There is need for more restorative dentistry among the low income group

**Hospitals**—In no case has there been any refusal to hospitalize patients regardless of their financial status

*Health and Relief Agencies*—There is need for additional funds to provide medical care for persons with infectious diseases, especially venereal diseases, and for persons with chronic illnesses who need institutionalized care. Some arrangement is needed to enable relief agencies to provide medical care for transients and nonresidents who are now ineligible for county aid.

*Health Departments*—An increase in the county budget to provide more medical care for the indigent and persons in the low income group would solve the problem.

*Schools*—School children have adequate medical care. There is a need for a free dental clinic supported by public or private funds.

*Other Organizations*—In the Houston district 218 business establishments assist and encourage their employees to become members of group hospitalization plans that are offered by

insurance companies. Other business organizations have employees' mutual benefit associations that pay sickness and death benefits to members or members' dependents.

*Pharmacists*—There is adequate medical service available for the people in all income groups at fees they are able to pay. The indigent are provided for through the relief agencies or at free clinics. There is a great need for a filter system that will prevent the people who can afford to pay from obtaining medical care at the free clinics.

Too many people go without medical care because the physicians will not help them to obtain free care.

*Nurses*—There is need for a medical social service filter system to determine eligibility of persons in the low income group for free care or for medical services at rates commensurate with their ability to pay.

## THE PHYSICIAN'S INCOME TAX—1939

*Prepared by the Bureau of Legal Medicine and Legislation*

This discussion relates only to the requirements of the federal income tax law. Information with respect to the requirements of state income tax laws should be obtained from responsible state sources.

The Revenue Act of 1938 amended in numerous respects the prior income tax law, but none of the changes made relate to physicians as a class distinct from the main body of federal income tax payers.

Every one who is required to make a federal income tax return must do so on or before March 15, unless an extension of time for filing his return has been granted. For cause shown the collector of internal revenue for the district in which the taxpayer files his return may grant such an extension, on application filed with him by the taxpayer. This application must state fully the causes for the delay. Failure to make a return may subject the taxpayer to a penalty of 25 per cent of the amount of the tax due.

The normal rate of tax on residents of the United States and on all citizens of the United States regardless of their places of residence is 4 per cent on net income in excess of the exemptions and credits.

### WHO MUST FILE RETURNS

1 If gross income was less than \$5,000 during 1938, a return must be filed (a) by every unmarried person, and by every married person not living with her husband or his wife, whose net income was \$1,000 or more, and (b) by every married person living with her husband or his wife whose net income was \$2,500 or more. If the aggregate net income of husband and wife, living together, was \$2,500 or more, each may make a return or the two may unite in a joint return.

2 Returns must be filed by every person whose gross income in 1938 was \$5,000 or more, regardless of the amount of his net income and of his marital status. If the aggregate gross income of husband and wife, living together, was \$5,000 or more they must file either a joint return or separate returns, regardless of the amounts of their joint or individual net incomes.

If the status of a taxpayer, so far as it affects the personal exemption or credit for dependents, changed during the year, the personal exemption and credit must be apportioned, under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury, in accordance with the number of months before and after such change. For the purpose of such apportionment a fractional part of a month should be disregarded unless

it amounts to more than half a month, in which case it is to be considered as a month.

As a matter of courtesy only, blanks for returns are sent to taxpayers by the collectors of internal revenue, without request. Failure to receive a blank does not excuse any one from making a return, the taxpayer should obtain the necessary blank from the local collector of internal revenue.

The following discussion covers only matters relating specifically to physicians. Full information concerning questions of general interest may be obtained from the official return blank and from the collectors of internal revenue.

### GROSS AND NET INCOMES WHAT THEY ARE

*Gross Income*—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, plus such money as he has received as profits from investments and speculation and as compensation and profits from other sources.

*Net Income*—Certain professional expenses and the expenses of carrying on any enterprise in which the physician may be engaged for gain may be subtracted as "deductions" from the gross income, to determine the net income on which the tax is to be paid. An "exemption" is allowed, the amount depending on the taxpayer's marital status during the tax year as stated before. These matters are fully covered in the instructions on the tax return blanks.

*Earned Income*—In computing the normal tax, but not the surtax, there may be subtracted from net income from all sources an amount equal to 10 per cent of the earned net income, except that the amount so subtracted shall in no case exceed 10 per cent of the net income from all sources. Earned income means professional fees, salaries and wages received as compensation for personal services, as distinguished from receipts from other sources.

The first \$3,000 of a physician's net income from all sources may be regarded under the law as earned net income, whether it was or was not in fact earned within the meaning set forth in the preceding paragraph. Net income in excess of \$3,000 may not be claimed as earned unless it in fact comes within that category. No physician may claim as earned net income any income in excess of \$14,000.

## DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. So far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed.

**Office Rent**—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in his dwelling house or apartment, he may not however, deduct any part of the rent of such house or apartment as professional expense, to entitle him to such a deduction he must have an office there with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

**Office Maintenance**—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants, are deductible.

**Supplies**—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using, for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies, and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value then purchase price is a capital expenditure and is not deductible.

**Equipment**—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment, such as is described above, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation deductions taken year by year over its useful life, as described below.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of

articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year, ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year, office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price or, if purchased before March 1913, either its fair market value as of that date or its original cost, whichever may be greater. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in his individual case.

In a Treasury Decision, approved Feb. 28, 1934, No. 4422, it is held, among other things, that

1 The cost to be recovered shall be charged off over the useful life of the property.

2 The reasonableness of any claim for depreciation shall be determined on the conditions known to exist at the end of the period for which the return was made.

3 Where the cost or other basis of the property has been recovered through depreciation or other allowances, no further deduction for depreciation shall be allowed.

4 The burden of proof will rest on the taxpayer to sustain the deduction claimed.

5 The deduction for depreciation in respect to any depreciable property for any taxable year shall be limited to such ratable amount as may reasonably be considered necessary to recover during the remaining life of the property the unrecovered cost or other basis.

Particular attention is called to the last of the foregoing provisions. If, in prior years, rates have been claimed which, if continued, will fully depreciate the cost, less salvage, before the end of its useful life, based on conditions now known, a reestimate of the remaining useful life should now be made and the portion of the cost that had not been depreciated at the beginning of the year 1938 (for a return for the year 1938) should be spread over this reestimated life.

**Medical Dues**—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

**Postgraduate Study**—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

**Traveling Expenses**—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

**Automobiles**—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance,

repairs, garage rental (when the garage is not owned by the physician), chauffeurs' wages, and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is in the possession of the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses, he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood.

What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

#### MISCELLANEOUS

*Contributions to Charitable Organizations*—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. A physician may not, however, deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

*Social Security Taxes*—The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them

within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid, but as an ordinary business expense.

*Laboratory Expenses*—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

*Losses by Fire or Other Causes*—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

*Insurance Premiums*—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

*Expense in Defending Malpractice Suits*—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

*Sale of Spectacles*—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold. Entries on the physician's account books should in such cases show charges for services separate and apart from charges for spectacles, etc.

## TAX RETURNS DUE UNDER THE SOCIAL SECURITY ACT

Physicians, medical associations and hospitals subject as employers to the taxes imposed by the Social Security Act, are again reminded that periodic tax returns must be made to the collector of internal revenue of the revenue district in which they are located. A tax return with respect to federal old age benefit taxes is required every month and an informational return every quarter. The monthly return for December 1938, required of every employer of one or more employees subject to the act, must be filed not later than January 31 on form SS-1. When this return is made the employer must pay to the collector the tax due from himself and all taxes imposed on his employees for the collection of which he is by law made responsible. The quarterly information return, for the quarter ended Dec 31, 1938, must be filed on or before January 31 on forms SS-2 and SS-3.

Tax returns with respect to federal unemployment compensation taxes are required annually of all non-exempt employers of eight or more persons subject to the act. The return for the calendar year 1938 must be filed on or before January 31 on form 940. With this return the employer may transmit to the collector the entire tax due or he may pay at that time one fourth of the tax and the remainder quarterly in equal installments as in the case of income taxes.

Copies of required forms and information concerning the returns may be obtained from the office of the collector of internal revenue. A failure to file a tax return subjects the delinquent employer to a penalty of from 5 per cent to 25 per cent of the tax due, depending on the period of delinquency, and, in case of a wilful refusal to file the return and pay the taxes, to criminal prosecution. Returns should be filed promptly.

## OFFICIAL NOTES

## RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis, that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

January 18	Scarlet Fever	Measles and Whooping Cough
January 25	Smallpox and Diphtheria	
February 1	Preventing Epidemics	

<sup>1</sup> Owing to program conflicts there will be no Chicago broadcast of the network program. Instead a recording of the program will be broadcast over station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## THE ST LOUIS SESSION

## Chairman of Local Committee on Arrangements

Dr Robert E. Schlueter, St. Louis, will serve as chairman of the Local Committee on Arrangements for the St. Louis session, which will be held May 15-19.

## Applications for Hotel Reservations

The Subcommittee on Hotels of the Local Committee on Arrangements has furnished a list of St. Louis hotels and rates for rooms which may be found on advertising page 43 of this issue of THE JOURNAL together with an application form that may be used to secure reservations through the Subcommittee on Hotels. The form that is printed in the advertising pages may be clipped and, when properly filled in, should be sent at once to Dr. Neil S. Moore, Chairman of the Subcommittee on Hotels of the Local Committee on Arrangements, 910 Syndicate Trust Building, St. Louis, Mo.

If those who expect to attend the annual session of the American Medical Association will send in their applications at the earliest possible time, there should be no difficulty encountered in securing satisfactory accommodations. Applicants for reservations are especially requested to include a second and a third choice in order that good accommodations may be assured if the desired reservation cannot be had at the hotel of preference. It will greatly expedite matters if requests for reservations are addressed directly to Dr. Moore.

## MEDICAL ECONOMIC ABSTRACTS

WISCONSIN EXPERIMENT IN  
COOPERATIVE MEDICINE

The Douglas County Medical Society, in cooperation with the State Medical Society of Wisconsin and the Cooperative Health Association at Superior, has concluded an agreement to provide members of the association with complete medical and surgical care on a prepayment basis for a period of trial and study.

In the preface to the agreement that was signed the following statements were made:

In September 1938 the State Medical Society of Wisconsin adopted the report of its Special Committee to study the distribution of health service and sickness care in Wisconsin. That report recommended that there be instituted under the direction of a special committee and the local county medical society and with the assistance of lay groups actively interested in proposals dealing with new methods of the delivery of sickness care experimental voluntary plans providing sickness care on a prepayment and voluntary basis. To assure that any such plan create no health hazard to those seeking services under it and to make certain that any subscriber should obtain those services contracted to be given even though the fee basis should prove inadequate and the compensation not that which the Cooperative expects the State Medical Society adopted as a requirement that the local medical society stand guarantor that the services be given and their quality be high. In other words the actual reserve would be the physicians of the community. The State Medical Society of Wisconsin and the Douglas County Medical Society have agreed that the Cooperative Health Association of Superior offers a proper situation for such experiment and thus the two medical societies and the Cooperative state these principles in the form of articles of agreement to be followed in developing such a voluntary plan in Superior Wisconsin.

The agreement provides that those who become members of the Cooperative Health Association shall have free choice of physician among the members of the Douglas County Medical Society, that a joint conference committee be established to meet regularly to discuss problems that may arise that not more than 20 per cent of the membership dues shall be subject to administration charges, that 80 per cent of the gross income should be earmarked for physicians' services, and that no more than 300 units would be encompassed in the trial. Units may represent individual membership or family memberships. The total number of people participating in the trial, it is estimated, will reach a total of 1,200 individuals. The amount of monthly dues has not as yet been established by the Cooperative Health Association. However, \$3 a month for complete medical and

surgical care for an entire family has been tentatively considered. For a couple or for a single person the dues would be less. The plan does not include hospitalization costs, as the members of the association plan to avail themselves of the statewide group hospitalization plan now being effected by the society in cooperation with the hospital associations. The society emphasizes that the premiums established were accepted by it "without expression of judgment" as to sufficiency. The plan does not limit the participants to any stipulated income group.

COOPERATIVE PLANNING IN  
PENNSYLVANIA

The committee of the Medical Society of the State of Pennsylvania has studied the work of the Emergency Child Health Committee to make recommendations to the state society as to future policies. The committee has worked in the closest cooperation with Samuel McClintock Hammill, chairman of the Emergency Child Health Committee.

When this work began, says Dr. Ben L. Hull in the *Pennsylvania Medical Journal* 42:237 (Dec.) 1938, in practically no county was there a well developed, coordinated effort on the part of the medical profession and other health agencies. As the result of a misunderstanding of one another's functions, in the majority of the counties there was definite antagonism between the profession on the one hand and the privately and publicly supported agencies on the other. In addition, the various privately and publicly supported agencies in the counties were competing among themselves rather than cooperating, which resulted in duplication of effort and inefficient service. These differences have been smoothed out largely, and the leadership of the medical profession and its willingness to cooperate with other agencies has been definitely established and deeply appreciated.

The most striking feature of the work has been, however, that it has opened up a new field of service in that the effort has been directed toward the protection of health rather than the cure of disease. This does not mean that the sick have been neglected because the various county committees have provided curative services where they were needed, whenever unsuspected handicapping defects have been recognized, provision has been made for their correction.

By Sept 15, 1938, a total of 148,143 children had been examined and 422,147 defects had been discovered. Of this number, 45.4 per cent have been corrected.

The physicians are encouraged to join the boards of welfare groups and assist in shaping their programs along the lines of medical leadership and interest them in directing their efforts to the financing of the corrective measures in the indigent and of assisting in getting in contact with families in the borderline and well-to-do groups and securing appointments with their family physicians at regular intervals.

The plan visualizes a strong central governing committee in the state society known as the Child Health Committee, with a similar committee in each county society. We have found that this type of medical leadership was always welcome.

In the actual working of the program among this class of people the parent-teacher associations, the tuberculosis societies and the child welfare leagues could all be well utilized in getting the children to the office of the family physician, in conveying back to the parents the necessary recommendations for correction that the physician has made, and in seeing that those corrections are carried out.

### POLITICAL HEALTH INSURANCE IN NEW ZEALAND

An editorial in the *New Zealand Medical Journal* (37:239 [Oct] 1938) tells how health insurance came to New Zealand. The first approach was the appointment of an investigation committee to hear evidence. This committee consisted entirely of members of one political party in the lower house of parliament. Its chairman was a member of the medical profession whose highest qualification was a political one and who dominated the committee. The report was kept secret, especially from all representatives of the medical profession.

The medical profession appointed a special committee of men of high standing and experience to draw up a plan for national health insurance suited to the conditions of practice in New Zealand. This committee's plan was then approved by the British Medical Association and presented to the government for its consideration and study. The plan was given scant if any real consideration by the government of New Zealand. Many months after its presentation to the government the responsible ministers concerned had not even read it. There were some discussions between representatives of the medical profession and the Ministers of Finance and Health but at no time was any information presented to the medical representatives concerning the government's proposal, except that the Minister of Finance was in favor of a universal scheme. The profession stressed the necessity for a service to the people unable to make full provision for themselves and pointed out that an incomplete medical service was grossly inefficient. The minister of finance constantly reiterated his determination not to allow in any circumstances any difference in medical treatment or in the personal attention given by the medical attendant. The profession sought to build up medical treatment to the highest level for all but the politicians were determined to bring down medical treatment to a strictly uniform level notwithstanding that this must develop uniformity of a low standard.

During all the discussions the committee showed a marked antipathy to the medical profession, and it became clear that the government did not desire to hear any evidence not in favor of its own proposals.

It may be stated, therefore, that the government has placed on the statute book the most far-reaching legislation of its kind ever drafted by a government anywhere in the world with the most incomplete preparation. The legislation has been evolved on the recommendation of an investigation committee of almost incredible inefficiency for the task allotted to it. The representations of the medical profession have not been seriously considered in the matter of major policy. The act determines the complete socialization of the profession and institutes a system of medical service which has aptly been described as 'demoralizing to those that give it and destructive to those that receive it—a service providing for the poorest type of treatment known to the medical profession, and this type is to be universal throughout the community.'

There can be no doubt as to the profession's duty to the country in this matter. For the benefit of the health of the people of New Zealand in the future, and for the preservation of all that is best in the profession of medicine, it is its duty to oppose to the uttermost this ill conceived measure so strongly tainted by party politics.

### COST OF PNEUMONIA TREATMENT

A study of the records of 625 pneumonia cases in New York City is reported by Joseph Hirsh in *Public Health Reports* (53:2153 [Dec 9] 1938). The cases were studied in terms of those factors in diagnosis and treatment to which monetary value can be assigned. The schedule used included (1) days hospitalized, (2) duration of illness, onset, admission, discharge, (3) serum (in units), (4) oxygen (in liters, later translated in terms of tanks), (5) x-ray plates, (6) laboratory services, pneumonia and pathology, (7) surgery, (8) drugs, (9) miscellaneous therapy, (10) consultations. These items were then priced on a conservative basis lower than those actually charged by the hospitals whose records were used.

The average cost per patient was \$167.60. Because there were several unusually expensive cases, the median of \$134.16 is taken as more significant. If the total cost is divided according to the type of services rendered, it is found that hospital care constituted 40 per cent of the total ward cost, 53 per cent of the semiprivate and 50 per cent of the private. Physicians' services comprised 22 per cent of the total ward cost, 26 per cent of the semiprivate, 35 per cent of the private and 62 per cent of the home. Serum therapy comprised 24 per cent of the total ward cost, 11 per cent of the semiprivate, 5 per cent of the private and 10 per cent of the home. The cost of other services constituted 15 per cent of the total for ward cases, 10 per cent for semiprivate, 10 per cent for private and 28 per cent for home.

The two major items of cost are hospitalization and physicians' services, of which the latter is much less than the cost of hospitalization. For ward cases serum therapy constituted a larger proportion of total costs than physicians' services.

### THE COST OF DENTAL CARE UNDER HEALTH INSURANCE

The Chicago Dental Society commissioned Peter T. Swanish, commissioner of placement and unemployment compensation of the Illinois Department of Labor, to undertake an analysis of the material accumulated by the Industrial Diagnostic Service, which had been conducted by the Chicago Dental Society as a measure of public health education. The study embraces 4,211 persons for whom dental work was done. The required information for use in the computations in this study was available for 1,308 females and 2,412 males.

The average length of time since the females included in the sample last visited a dentist was eighteen months, as compared with 32.9 months in the case of males. Women visit a dentist about 183 times as often as men. Over 65 per cent of the females included in the 1,308 cases visited a dentist within one year or less, 81.7 per cent within an interval of two years or less, 88.5 per cent within an interval of three years or less, 92.0 per cent within an interval of four years or less and 94.7 per cent within an interval of five years or less.

Actual dental need was defined as treatment considered actually necessary to safeguard the health of the person at the time of examination. To provide for the actual dental needs of the 4,211 individuals included in this sample would require in round sums an outlay out of the funds of a health insurance plan of \$48 for females, \$55 for males and \$53 for males and females combined.

Complete roentgenograms of the mouths of 4,211 persons were examined and reduced to dollar terms by qualified technicians and dentists, a dollar figure arrived at in this manner should approximate the actual dental needs of that large number of working men and women in whose behalf such plans are adopted or urged. A health insurance plan should undertake to meet the actual dental needs of persons covered by the scheme,

1 Swanish, Peter T. The Cost of Dental Care under Health Insurance. Chicago Dental Society, 1938.

would be obliged to expend on an average the sums indicated. In face of the tremendous fiscal obstacles in the way of a plan organized to provide for the actual dental needs of men and women, it is highly probable that a health insurance plan would be forced of necessity to limit itself to providing preventive treatment only. If we accept the arithmetical mean figure as the measure of dental need, and there is no good reason why it should not be accepted, then it is clear that no health insurance plan yet devised or placed in operation even pretends to provide for the actual dental needs of those embraced under such schemes. It is also quite clear that all such plans are organized to provide dental treatment of a preventive character and nothing more.

In 1931 the average per capita expenditure in Germany for cash and maternity benefits, hospital care, medical and dental treatment, medicines and drugs, funeral benefits, administrative and other costs was \$18.69. Of this total 5.08 per cent, or approximately 95 cents per capita was spent for dental care. Under the sickness insurance system in Denmark, a voluntary

scheme, the per capita outlay from recognized "sickness funds" in 1930 was \$7.51. Out of the \$7.51, 3.18 per cent, or roughly 24 cents, was spent for dentistry.

From the magnitude of these outlays it seems reasonable to infer that health insurance as one of several integral parts of a broader scheme to provide social security is also a device intended to insure political security and, together with all the other component measures included in social security plans, seems to rest on the assumption that a small dose of economic security will assure an adequate measure of political stability, and that while accomplishing the latter it will act to stalemate desire on the part of industrial workers at large for change of a more revolutionary nature.

As a practical proposition involving a fiscal burden of enormous proportions, a health insurance plan could not go beyond preventive care. The simple arithmetic of the matter suggests that even with a health insurance plan in operation there would still remain a vast amount of dental treatment for the private practitioner to supply.

## MEDICAL LEGISLATION

### Massachusetts

**Bills Introduced**—H. 287 proposes as a condition precedent to the issuance of a license to marry that each applicant present a statement signed by a licensed physician that he or she has submitted to a Wassermann or Kahn or similar blood test and that in the opinion of the physician, he or she "is not infected with syphilis or in a stage of that disease that may become communicable." The statement of the physician is to be accom-

panied by a record of the standard laboratory blood tests made. H. 288 proposes to prohibit the sale of any medicine "which in and of itself contains enough poison or other deadly drug so that if taken in whole or in part is sufficient to cause the death of the person taking it" unless the container shall be so labeled as to state the nature of the poison or the deadly drug, what quantity thereof would constitute a lethal dose, and the antidote therefor.

## WOMAN'S AUXILIARY

### Arkansas

The auxiliary to the Sebastian County Medical Society met in Fort Smith October 10 and voted to place *Hygiene* in the Girls' club, the Carnegie library, the Rosahe Tilles Children's home, the Y M C A and twelve rural schools.

The auxiliary to the Washington County Medical Society held a dinner meeting at Fayetteville, November 1. Following the dinner and program, members worked on supplies for the City Hospital.

### Louisiana

The principal project of the auxiliary to the Caddo Parish Medical Society is sponsoring the education of children in the Pines Preventorium for the tuberculous. Other projects are *Hygiene*, Doctors' Day, Southern medical history, periodic health examination and a fund to aid indigent physicians.

### Minnesota

The auxiliary to the Minnesota State Medical Association held an executive board meeting at Minneapolis September 26. The speakers were Mrs. Charles C. Tomlinson, president of the auxiliary to the American Medical Association, and Dr. J. M. Hayes, president of the Minnesota Medical Association.

### Mississippi

The auxiliary to the Mississippi State Medical Society has decided to raise a fund of \$5,000 to finance the purchase of certain needs of the state preventorium for the care of children. The goal is to complete the fund before the annual meeting in Gulfport in 1939.

### Missouri

Dr. Robert E. Schluter, St. Louis, spoke at a meeting of the auxiliary to the St. Louis County Medical Society October 11 on "Recent Developments in Medical Science." The presidents of the women's clubs of the city were guests.

The auxiliary to the Buchanan County Medical Society has reported that 103 subscriptions to *Hygiene* were placed in schools in the county. The auxiliary contributed \$15 to the essay fund of the state auxiliary.

### New York

The auxiliary to the Medical Society of the County of Kings held its first annual health institute at the county medical society building, 1313 Bedford Avenue, Brooklyn, October 11. Among the speakers were Dr. John B. Dalbora, president, Medical Society of the County of Kings; Dr. Matthew Walzer, "Are You Allergic?"; Dr. Walter Truslow, "What Price Feet?"; Dr. George H. Roberts Jr., "Heartaches" and a demonstration of the value of electrocardiograms; Dr. LeGrand Kerr, "Why Immunize the Child?"; Dr. Charles A. Gordon, "Maternal Welfare", motion picture, "The Birth of a Baby".

Mr. F. Davis, superintendent of Nassau Hospital, spoke on "Hospitalization and the Medical Plan" in the Nassau Hospital Auditorium October 18 before the auxiliary to the Nassau County Medical Society.

### Oklahoma

The auxiliary to the Pottawatomie County Medical Society met in Shawnee September 28. An address on auxiliary work was given by the president, Mrs. Clinton Gallaher.

The auxiliary to the Oklahoma County Medical Society held a registration tea in Oklahoma City September 30 with 150 members in attendance. The first monthly sewing and business meeting was held at the Y W C A October 26 with ninety-five members present. The auxiliary furnishes clothing for the State Hospital for Crippled Children.

### Texas

The auxiliary to the Northwest Texas District Medical Society met in Breckenridge September 13. Dr. T. C. Terrell, Fort Worth, counselor for the thirteenth district, spoke on socialized medicine.

The auxiliary to the Bell County Medical Society held a meeting at the home of Dr. and Mrs. G. V. Brindley, Temple, October 14. Mrs. F. F. Kirby outlined the aims of the auxiliary, emphasizing health education, student loan funds and the promotion of friendships among the families of doctors. One hundred and forty members of the county auxiliary were present.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

### ALABAMA

**Society News**—Dr Tinsley R Harrison, Nashville, Tenn, addressed the Madison County Medical Society, Huntsville, recently on "Use and Abuse of Drugs in the Management of Cardiac Disease." Dr Joseph E Hirsh, Birmingham, discussed "Medical Treatment of Peptic Ulcer with Special Reference to Histidine" before the society recently. At a meeting of the Tuscaloosa County Medical Society November 14 Dr James M Mason, Birmingham, spoke on empyema and Dr James William MacQueen, Birmingham, standardization of hospitals.

**Changes in Health Officers**—Dr Jack A Crittenden, Elba has been appointed health officer of Coffee County, succeeding Dr William A Dodson Jr, who resigned on account of ill health. Dr Martie F Parker, Greenville, has been named health officer of Butler County to succeed Dr Charles J Fisher, who is taking graduate work at the Johns Hopkins School of Hygiene and Public Health, Baltimore. Dr Hugh G Clark, Lafayette, has been appointed health officer of Chambers County. He succeeds Dr Abraham I Perley, who was awarded a year's graduate study at Harvard University.

### CALIFORNIA

**Medical Care for Needy Transients**—The Agricultural Workers' Health and Medical Association, a recently established government agency to provide medical care for needy transients has been moved from Tulare to 1110 East Main Street, Visalia. The association dispenses federal funds, certifying to private physicians and private hospitals sick or injured transients who have not been in the state long enough to qualify for county aid.

**Society News**—The San Francisco County Medical Society was addressed January 10 by Drs Mayo H Soley, San Mateo, on "Differential Diagnosis Between Hyperthyroidism and Heart Disease" and Howard A Brown and Jesse L Carr, "Cerebral Anoxemia Resulting from Nitrous Oxide Anesthesia." Dr George R Herrmann, Galveston, Texas, addressed the Los Angeles Clinical and Pathological Society November 16 on "The Clinical Nature of Heart Failure."

### CONNECTICUT

**Changes in Health Officers**—Dr Samuel S Farago, Westerly, R I, has been appointed health officer of Pawcatuck succeeding the late Dr William A Hillard. Dr Helen Baldwin has been appointed health officer of Canterbury. Dr Charles Flynn is now acting health officer of Hamden. Dr George H Joslin was formerly health officer of Hamden. Dr William Sherman Randall is health officer of Shelton, filling the unexpired term of the late Dr John Eugene Black. Dr Donald J McCrann West Hartford, has been appointed health officer of Bloomfield replacing Dr Maurice B Thompson, who has moved to New York to engage in full time medical insurance work, according to the *New England Journal of Medicine*. Dr Archibald M Gaulocher, Wingdale, N Y, has been appointed health officer of Kent and Dr Frank D Ursone, Norfolk, of Colebrook. Dr Edward J Brophy, Norwich, is completing the unexpired term of the late Dr Harrison Gray.

### DISTRICT OF COLUMBIA

**Society News**—The Georgetown Clinical Society and the George Washington University Medical Society presented a symposium on practical considerations of common problems in obstetrics and gynecology before the Medical Society of the District of Columbia December 14. *THE JOURNAL*, January 7, erroneously reported that the Georgetown University Medical Society cooperated in the program. Dr Charles Joseph Horgan discussed "The Surgical Consideration of the Redundancies of the Colon" in his presidential address before the Washington Medical and Surgical Society, Washington, recently. Dr Horgan retired as president at this meeting.

### FLORIDA

**Personal**—Dr Lucien Y Dyrenforth, Jacksonville, was recently made chairman of the committee on the biologic sciences of the Florida Academy of Sciences. Dr Edward Jelks, Jacksonville, was elected chairman of the technical advisory committee to the Florida Crippled Children's Commission at a meeting in Jacksonville December 1.

**Hospital News**—The Lake County Medical Center was formally dedicated in Eustis November 6. The new hospital is under the supervision of the Lake County Medical Society and was made possible by a gift of the late Frank D Waterman, who donated \$145,000 worth of bonds on the Foundation Inn Building to the Lake County Medical Center, consisting of ten stockholders, all members of the county medical society. Speakers at the dedicatory ceremonies included Dr William Henry Spiers, Orlando, president of the state medical association, Senators C O Andrews and Claude Pepper, and Mayor Gaylord of Eustis.

**District Meeting**—The second annual meeting of the South Central Medical Society was addressed in Eustis recently, among others, by the following:

Dr Lester L Whiddon Fort Pierce Practical Odds and Ends  
Dr William O Fowler, Orlando Artificial Pneumothorax Its Technique Value and Usage  
Dr Thomas C Kenaston Cocoa Coronary Thrombosis in General Practice  
Dr Thomas M Rivers Kissimmee Relation of the Sympathetic Nervous System to Health and Longevity

Dr William P Nicolson Jr, Atlanta, addressed the evening meeting on "Cancer of the Breast, Its Diagnosis and Management." The Lake County Medical Society acted as host.

### GEORGIA

**Society News**—At a meeting of the Fulton County Medical Society, Atlanta, November 17 the speakers included Drs Lonnie W Grove and Kenneth R Bell on "Surgical Diseases of the Spleen," and Calvin B Stewart, "Cancer of the Lip." The society was addressed November 3 by Dr David Henry Poer on "Recent Developments in the Treatment of Thyroid Conditions", Dr Arthur Park McGinty and W Elizabeth Gambrell, Ph D, presented a paper entitled "Chronic Brucellosis."

**District Meeting**—At a meeting of the Eighth District Medical Society in Douglas recently the speakers included Drs Franklin G Eldridge, Valdosta, "Malaria Control", Benjamin H Minchew and Braswell E Collins, Waycross, "Further Study of the Social Aspect of Strabismus", Grady N Coker, Canton, president of the state medical association, "Our Problems", Thomas H Johnston, Douglas, "The Technique of Local Anesthesia", Charles H Watt, Thomasville, "A Modified Well Leg Traction Splint and Distractor Combined," and William F Reavis and L W Pierce, Waycross, "Prostatic Obstruction."

### ILLINOIS

**New County Society**—A tricity medical society, embracing Pope, Johnson and Massac counties has been organized with Dr Lewis S Barger, Golconda, as president. Dr Virgil O Decker, Metropolis, was chosen vice president and Dr Joseph A Fisher, Metropolis, secretary.

### Chicago

**Society News**—Dr Morris Fishbein, Editor of *THE JOURNAL*, will address the Rotary Club of Chicago at the Hotel Sherman January 31 on "The Social Aspects of Medical Care." Paul H Douglas, Ph D, professor of economics, University of Chicago, addressed the club January 3 on "The Need for Better Medical Service."

**Personal**—William Baker Day, Ph M, dean of the University of Illinois College of Pharmacy since 1920, died December 10 in Oak Park, aged 67. Professor Day was professor of histologic botany from 1898 to 1913 and was acting dean and professor of botany and materia medica from 1913 to 1919. He was president of the American Pharmaceutical Association in 1912 and secretary from 1914 to 1925. For several years he was secretary of the board of trustees of the U S Pharmacopeial Convention.

**Medical Counselor Appointed**—The Chicago *Tribune* has appointed Dr Frederick W Fitz, a member of the staff of Passavant Hospital, as medical counselor for its employees. Dr Fitz graduated at Northwestern University Medical School in 1934. The counselor's services will be controlled by the Dearborn Mutual Benefit Association, an employees' organization the cost to be met by the *Tribune* company. The counselor's services will be entirely advisory. He will not treat or prescribe.

for or become the personal physician of any employee or member of any employee's family. According to the *Tribune*, the counselor's duties will be

- 1 To confer with employees who wish to consult him about their personal medical problems or those of their families
- 2 To advise when requested as to competent physicians in all parts of the city and suburbs and to maintain a list of such physicians men known to possess not only skill but a high sense of honor and integrity whose fees will be in accordance with the employees' capacity to pay
- 3 To assist in arranging for surgical procedures hospital accommodations and so on
- 4 To act when the employee or his family desires as an agent between them and the physician they select. The counselor's medical knowledge would assure a fair answer to such questions as the necessity for a proposed operation
- 5 To cooperate in assuring employees fair charges on the part of physicians surgeons hospitals and nurses
- 6 When an employee so requests to check any diagnosis brought him by the employee either by conference with the physician making it or by reference to the symptoms leading to the diagnosis
- 7 To advise on group health problems of employees and inspect work conditions in departments of the *Tribune*

## INDIANA

**County Societies Expand Activities**—The Lake County Medical Society now sponsors a survey of venereal diseases in the county and a plan with a reputable insurance organization offering hospital and voluntary sickness insurance, according to the state medical journal. The employment of a full time executive secretary in Hammond has also been approved. The Vanderburgh County Medical Society also recently voted to reorganize. Expanded activities will include the employment of a full time executive secretary and a new plan for medical care, it is reported.

## IOWA

**Society News**—At a meeting of the Des Moines Academy of Medicine and the Polk County Medical Society, Des Moines, October 25, the speakers were Drs. Guy C. McFarland Jr., Ames, and Donald H. Kaump on 'Low Back Pain and Epiaero-iliac Lipoma' and 'Leukemoid Reactions' respectively. Dr. John P. Peters, New Haven, Conn., addressed the Linn County Medical Society in Cedar Rapids December 15 on 'Nephritis' and 'Medical Economics'.

**Laboratory Courses for Study of the Pneumococcus**—The state department of health conducted a laboratory course for study of the pneumococcus and of diagnostic procedure for type determination of pneumonia in the Medical Laboratories Building, Iowa City, December 6-9 and 14-16. The course was given by Dr. Milford E. Barnes, director of the state hygienic laboratory, assisted by Dr. Irving H. Borts, bacteriologist in charge, and other staff members. According to the state medical journal, the course affords an opportunity for hospital and laboratory workers, technicians and physicians in all parts of the state to become more familiar with the Neufeld method. Limited funds were available through the U. S. Public Health Service to finance part of the expenses of laboratory technicians who registered for the course. A third course may be given this month.

## MASSACHUSETTS

**Graduate Extension Courses**—The Massachusetts Medical Society, the state department of health, the U. S. Public Health Service and the U. S. Children's Bureau are sponsoring a series of medical graduate extension courses throughout the state. The current series will be offered in New Bedford, Lawrence, Salem, Northampton, Quincy, Brockton, Milford and Fitchburg. Courses in the remainder of the state will be conducted during the winter and spring months. Subjects will include anemia, Bright's disease and hypertension, heart diseases, gonorrhea, syphilis, obstetrics and pediatrics.

**Dr. Wilhelm Superintendent of Peter Bent Brigham Hospital**—Dr. Norbert A. Wilhelm, superintendent of Butterworth Hospital, Grand Rapids, Mich., has been appointed superintendent of Peter Bent Brigham Hospital, Boston, succeeding Dr. Joseph B. Howland. A graduate of St. Louis University School of Medicine, class of 1925, Dr. Wilhelm served as second assistant superintendent of Peter Bent Brigham Hospital from July 20, 1930, to March 5, 1934, when he was named first assistant, this position he held until April 1, 1937, when he went to Grand Rapids. Dr. Howland graduated at Harvard University Medical School, Boston, in 1896 and has been superintendent of Peter Bent Brigham Hospital since May 1, 1919. The change was effective January 1.

**Society News**—Dr. William Dameshek discussed 'The Relations of Hematology to Dermatology' before the New England Dermatological Society in Boston December 14. The Massachusetts Society of Examining Physicians was

addressed December 14 by Robley D. Evans, Ph.D., Cambridge, on 'Some Health Hazards in the Use of Radioactive Substances,' and Dr. William J. Brickley, Boston, 'A Comparison of the Practice of Medicine and the Practice of Law.'—Dr. Channing Frothingham, Boston, addressed the William Harvey Society of Tufts College Medical School, Boston, November 18 on 'The Economic Side of Medicine.'—Dr. Charles H. Shamlian discussed 'Asphyxia: Its Prevention and Treatment' before the Eastern Hampden Medical Association recently in Springfield.

## MICHIGAN

**Study of Hospital Needs in Detroit**—A study of the Detroit hospital situation recently completed by Dr. Jacob J. Golub, director of the Hospital for Joint Diseases, New York City, indicates a need for more hospital beds. Dr. Golub's study was part of a survey conducted by the Council of Jewish Federations and Welfare Funds, Inc., at the request of the Jewish Welfare Federation to determine special aspects relating to the question of establishing a hospital under Jewish auspices in Detroit. Dr. Golub said that it is generally regarded as desirable for large cities to have five general beds for each thousand of population, at 80 per cent occupancy. Eight of the largest cities in the United States exceed that number. But Detroit, although occupying fourth place in the country on the basis of population, drops to tenth place from the standpoint of its ratio of hospital beds, taking its population at its 1930 census of 1,568,662. Because Detroit has grown rapidly and has a predominantly youthful population its relative shortage of hospital beds has not yet become noticeable. Between 1910 and 1920, a period of high industrial growth in the motor industry, Detroit's population rose 113 per cent. At the end of the decade between 1920 and 1930 the census rose to 1,568,662, an increase of 57 per cent. Because of this great influx, Detroit has a younger population than any other city in the country, 75.8 per cent being 40 or younger. The sickness rate per thousand people tends to increase with age. It is reported that on the average in any one day, among children 15 years of age, one in twenty-four is sick, among persons between the ages of 15 and 24 years one in forty is sick, among persons between the ages of 25 and 64, one in twenty-four is sick, and among persons 65 years and older, one in eight is sick. Dr. Golub's study points to the factor of increasing bed utilization in Detroit's forty-two hospitals with a capacity of 7,092 beds. The eleven general hospitals, with more than a hundred beds each, at present admit 77 per cent of the community's patients and are occupied 85 per cent of capacity. During several months of the year they have no vacant beds at all. When a hospital is on the average occupied from 80 to 85 per cent of its capacity it is, from the standpoint of community service, fully occupied. The difference between 80 and 85 or 100 per cent represents beds held for advance reservations for patients, beds vacated in the afternoon and not occupied by patients (on the waiting list and sent for) until the next morning, and beds held for emergency service. Since 1930, presumably because of the economic depression Detroit's rate of growth has lost its momentum and shows only a 5 per cent increase in 1936 over the 1930 census. This trend would indicate that Detroit's population is growing older, the bed utilization is rising and the shortage of facilities will soon become evident. Dr. Golub said there seems to be no good reason why the Jews should not participate in meeting the requirements of the sick in Detroit with reference to hospital care. He suggests the ultimate establishment of a 200 bed institution operating on the highest standards. 'The cost of erecting and equipping a 200 bed hospital would be close to \$1,000,000. A study of the problems in financing Dr. Golub's proposed hospital project has been prepared by Harry L. Lurie, executive director of the Council of Jewish Federations and Welfare Funds.'

## NEBRASKA

**Society News**—Dr. Stuart W. Harrington, Rochester, Minn., addressed the Omaha-Douglas County Medical Society, Omaha, December 13 on 'Surgical Treatment of Diaphragmatic Hernia' and Dr. John C. Sharpe on 'Treatment of Hemorrhagic Blood Diseases.' Dr. Frank W. Hartman, Detroit, addressed the society November 8 on anoxia and Dr. Frank M. Conlin 'Differential Diagnosis of Intrathoracic Tumors.'—Drs. Charles A. Owens and Harley E. Anderson, Omaha, addressed the Adams County Medical Society, Ingleside, November 3 on 'The Use of Sulfanilamide in Urology' and 'The Use of Cystography in Placenta Praevia.'

respectively—Drs Richard F. Richie and Roy H. Whitham, Lincoln, addressed the Lancaster County Medical Society November 1 on "Hysteria" and "Modern Gastric Surgery" respectively.

## NEW YORK

**Birth Certificates to Show Mothers' Blood Tests**—A law requiring that birth or stillbirth certificates indicate whether a blood test was made during pregnancy or at delivery became effective in New York January 1. This measure is a companion law to one also enacted in March 1938 providing for serologic blood tests of expectant mothers. The new birth certificate will give the date on which the blood test was made during pregnancy or if no test was made, the reason. The result of the test will not be given on the certificate.

**Fifty-One Years a County Secretary**—Dr Samuel W. Close, Gouverneur, was honored at a dinner December 4 by members of the St. Lawrence County Medical Society in recognition of his services as secretary for fifty-one years. Dr Frank F. Williams, Canton, was toastmaster and Dr Grant C. Madill, Ogdensburg, presented to Dr Close for the society a gold-headed cane bearing in appropriate inscription Dr Close graduated from New York University Medical College, New York, in 1885 and settled in Gouverneur in 1886. At a recent meeting of the society he was made secretary emeritus for life.

## New York City

**Harvey Lecture**—Edwin J. Cohn, Ph.D., professor of biological chemistry, Harvard University Medical School, Boston, will deliver the fourth Harvey Lecture of the current series at the New York Academy of Medicine January 19. His subject will be "Proteins as Chemical Substances and Biological Compounds."

**Dr Wilcox Appointed Director of Academy**—Dr Herbert B. Wilcox, professor of diseases of children at the College of Physicians and Surgeons of Columbia University, has been appointed director of the New York Academy of Medicine to succeed Dr John A. Hartwell, who has resigned. The change will take place April 1. At the annual meeting January 5 Dr Malcolm Goodridge was installed as president for a term of two years. The retiring president, Dr James Alexander Miller, in his address revealed that the academy had recently been asked to show why it should be exempt from federal income tax. After detailed examination the exemption was allowed. The academy has been exempt from all taxation since it was founded in 1847. The Medical Information Bureau, established in 1928, has now been raised to the status of a regular standing committee of the academy.

**Physicians' Club at the World's Fair**—Announcement is made of the formation of the Professional Club for physicians and public health workers at the New York World's Fair. Incorporators of the club were Drs James R. Reuling Jr., who was elected president, Edward R. Cunniffe and Matthias Nicoll Jr., White Plains, N. Y., vice presidents. Mrs W. R. Walsh, secretary, and Dr Benjamin Wallace Hamilton, treasurer. Club rooms will be provided on the main floor of the Medical and Public Health Building of the fair. Membership is open to accredited members of the American Medical Association and the American Public Health Association. Accredited representatives of organizations whose financial support has made possible the educational exhibits in the Medical and Public Health Building will also be members and it is expected that membership will be extended to other groups.

**Art Work by Hospital Patients**—An exhibition of paintings and drawings by patients in the psychiatric division of Bellevue Hospital was held at the Harlem Community Art Center in November under the auspices of the hospital and the WPA Federal Art Project. Teachers furnished by the federal art project have worked since the spring of 1935 with the patients under the supervision of the psychiatric staff, making notes on the behavior and remarks of patients during the periods devoted to art work. From the data thus obtained the physicians believe they have gained certain conclusions of value in the diagnosis, analysis and treatment of the patients. The exhibition consisted of 106 entries, grouped by case types covering both adults and children. Art classes have also been found beneficial to handicapped children at the Convalescent Home for Hebrew Children, Rockaway Beach, L. I. The work not only serves educational and recreational ends but has helped crippled children to recover the use of their fingers in many cases. It has also improved morale in the orthopedic ward, the home reported.

**Personal**—Dr Solomon Stan Bauch was elected president of the New York Physicians' Art Club at the annual dinner November 26, Dr Alfred Braun vice president and Dr J. R. Gudger secretary—Dr Rudolf Schindler, Chicago, gave the annual Herbert Swift Carter Lecture at Columbia University College of Physicians and Surgeons November 29 on "The Clinical Significance of Gastroscopy." Dr Schindler also lectured December 2 at Cornell University Medical College on "Gastroscopy with Special Reference to Its Value in the Fight Against Gastric Carcinoma" and November 30 before the New York Gastro-Enterological Association on "The Clinical Value of Gastroscopy." He addressed the New York Academy of Medicine on "Chronic Gastritis" January 5.—The medical board of St. Mary's Hospital, Brooklyn, sponsored a dinner in honor of Dr John Richard Kevin December 10 at the Hotel St. George, marking his fiftieth anniversary as a member of the staff.—Dr Joshua M. Van Cott, emeritus professor of pathology and clinical medicine, Long Island College of Medicine, was recently elected a member of the board of trustees. A graduate of the Long Island College Hospital in 1885, Dr Van Cott is president of the board of trustees of the Hoagland Laboratory.

## NORTH CAROLINA

**New City Health Building**—A building formerly used for a school in Winston-Salem has been remodeled as headquarters for the city's health services, it is reported. The city health department, the city-county venereal disease clinic, offices of the outpatient department of the city hospital and the medical work of the city department of welfare will be accommodated in the building. An addition was made for the city health department laboratory.

## OHIO

**Dedication of Hospital Unit**—Dedication of a new outpatient dispensary and contagious disease wing attached to the Starling-Loving University Hospital, Ohio State University College of Medicine, Columbus, was a feature of the annual clinics and homecoming November 19. The clinic will use four floors, and two floors will make up the unit for contagious diseases. One room is reserved for the respirator recently purchased with funds from the President's Birthday Ball.

**Conference of Health Commissioners**—The nineteenth annual conference of Ohio health commissioners with the state department of health was held in Columbus November 17-18. The guest speakers included Drs John Sundwall, Ann Arbor, Mich., on "Qualifications of Public Health Personnel", Allen W. Freeman, Baltimore, "Present Tendencies in Rural Health Organization," and Miss Pearl McIver, U. S. Public Health Service, Washington, D. C., "Making Public Health Nursing More Effective."

**Society News**—Dr Roy D. Arn, Dayton, addressed the Montgomery County Medical Society, Dayton, December 2 on "Appendicitis with Special Reference to the Treatment of Complicated Cases." Four thousand persons visited a "Hall of Health" sponsored by the society and the Y. M. C. A. department of physical education during the week of November 7.—Dr Guy H. Williams Jr., Cleveland, was elected president of the Association of Physicians of Ohio State Institutions at the recent annual meeting in Columbus, Dr Ewing H. Crawfis, Lima, vice president, and Milton P. Smith, Toledo, secretary.—Dr Frederick H. Falls, Chicago, addressed the Academy of Medicine of Cleveland December 16 on "Management of the Common Complications of Pregnancy."—Dr Robert D. Mussey, Rochester, Minn., addressed the Academy of Medicine of Cincinnati December 13 on "Progress and Conservatism in Obstetric Practice."

**Prescription Not Admissible in Evidence**—A physician's prescription cannot be received in evidence under the laws of Ohio except under the same circumstances as those that make the testimony of the prescribing physician admissible, according to Judge James S. Martin of the court of common pleas, Lucas County. A prescription the judge ruled, is within the contemplation of section 11494, Ohio general code, which prohibits a physician from testifying concerning communications made to him by his patient or his advice to his patient, in a professional relation, unless the patient expressly or impliedly consents to such testimony. The occasion of Judge Martin's ruling was a will contest (*Zwicker et al v. Leonard*, No. 153334) in which it was contended that the testator was not competent when he executed his will because of the continued use of narcotic medication. To

prove this contention, contestants sought to require the drug house which seemingly had filled the prescriptions of the attending physician to produce those prescriptions. This Judge Martin refused to require "The court," the judge stated in a journal entry, finds that such prescriptions are privileged under the law and not available as evidence in this action"

### PENNSYLVANIA

**Society News**—Dr Thomas H A Stites, Nazareth, among others, addressed the Westmoreland County Medical Society December 20 on 'Postgraduate Education'—Dr David H Ruben, Washington, addressed the Washington County Medical Society, Washington, December 14 on 'Urology in General Practice'—Dr Chauncey L Palmer, Pittsburgh, chairman of the committee on public relations of the Medical Society of the State of Pennsylvania, addressed the annual public health meeting of the Fayette County Medical Society, January 12 on 'Socialized Medicine'

### Philadelphia

**Jeanes Hospital Ten Years Old**—Jeanes Hospital celebrated its tenth anniversary at a meeting December 12 at the Friends' Meeting House. The speakers on the program were Drs Morris Fishbein, Chicago, Editor of THE JOURNAL on 'Importance of the Early Recognition of Cancer' and Wilmer Krusen, 'The Responsibility of the Public Regarding Cancer'. Mr Charles F Jenkins treasurer of the hospital recounted its history. Mr J Wilmer Lundy, president, introduced the program.

**Society News**—The annual Gross Lecture of the Pathological Society of Philadelphia was delivered by Dr Milton C Winternitz, New Haven December 8, on 'Further Studies on the Pathogenesis of Vascular Disease'. Plans for the third annual Pediatric-Pharmacy Week to be sponsored by physicians and pharmacists of Philadelphia during the week of May 1 were laid at a meeting November 7 at the Philadelphia College of Pharmacy and Science. Dr William N Bradley is chairman for physicians and Ambrose Hunsberger Ph M, for the pharmacists.

**Cancer Research Project**—The Women's Medical College of Pennsylvania has opened a cancer research project under which 1000 women will receive physical examinations twice a year for five years in an attempt to detect cancer or prevent its development. Clinics for the examinations will be held the second Thursday of each month under the supervision of Dr Catharine Macfarlane with the assistance of Drs Margaret C Sturgis and Julia Ruth S Fetteiman. No charge is made for the examination and all cases requiring treatment are referred to family physicians.

**Hospital News**—A new unit of St Christopher's Hospital for Children was dedicated November 30. Funds for the building were provided by a bequest of \$100,000 in 1931 by the late Joseph Bromley and one of \$150,000 by the late William B Scott, for many years president of the hospital. The Methodist Episcopal Hospital recently dedicated a new \$50,000 x-ray department of which Dr Milton F Percival is in charge. Coming lectures in the series presented by Mount Sinai Hospital will be

Dr Frank E Lentz, Rheumatism January 18

Dr Harry J Epstein, Syphilis—the Masquerader of Diseases February 15

Dr Charles S Wachs, Old and New Ideas of Childbirth, March 15

Dr Morris Weinstein spoke December 21 on 'Donts in Ear, Nose and Throat Conditions'

### Pittsburgh

**The Emmerling Lecture**—Dr Ralph Pemberton, Philadelphia, delivered the Drs Charles and Karl Emmerling Memorial Lecture at the Pittsburgh Academy of Medicine December 13 on 'The Syndrome of Arthritis'.

**Society News**—The child health division of the General Health Council of Pittsburgh sponsored a meeting in the interest of children with cardiac disturbances December 6. Dr Ann G Kuttner, resident physician at Irvington House for Cardiac Children, Irvington, N Y, was the guest speaker on 'The Care of Children with Rheumatic Heart Disease'. Dr John M Lichty discussed the local problem of this group. Among speakers at a meeting of the Pittsburgh Surgical Society December 16 were Drs Walter Scott Nettrour on 'Surgical Imports of Bile Acid Determinations for Liver Function' and Harold W Rusbridge and Grover C Weil, 'A Study of Surgical Management of Lipoma'. Dr John S Lewis Jr, Youngstown, Ohio, among others addressed the Pittsburgh Urological Association December 12 on 'Urine Drainage—Its Clinical Applications'.

### RHODE ISLAND

**Society News**—A panel discussion on "Cooperation in the Cancer Problem" was presented at a meeting of the Providence Medical Association November 7. Dr Herman C Pitts was chairman and the discussers were Drs Benjamin Earl Clarke, on the role of the pathologist, Peter P Chase, the surgeon, George W Waterman, the gynecologist, and Isaac Gerber, the radiologist. Dr Sylvester McGinn, Boston, addressed the Pawtucket Medical Association November 17 on 'Modern Treatment of Congestive Heart Failure'. Dr Irving J Walker, Boston, will speak January 19 on 'Clinical Aspects of Water Balance'.

### TEXAS

**Post-Graduate Assembly of Southwest Texas**—The annual International Post Graduate Medical Assembly of Southwest Texas will be held in San Antonio January 24-26. Sixteen instructors are listed in the program.

**Public Health Association Meeting**—The annual meeting of the Texas Public Health Association was held in San Antonio in November under the presidency of Dr Benjamin M Primer, Austin. Among the speakers were Drs Arthur T McCormack, Louisville, Ky, Clifford E Waller of the U S Public Health Service, Washington, D C, and Ernest W Bertner, Houston president of the Texas State Medical Association. Dr Walter Kleberg, health officer of Galveston, was elected president.

**Public Medical Meeting**—The Central Texas Medical Society sponsored a banquet meeting in Waco November 7 to which public officials and representatives of many civic groups were invited and physicians were asked to bring non-medical friends. The speakers were Drs Rosco G Leland, Chicago, director of the Bureau of Medical Economics, American Medical Association, Edward H Cary, Dallas, chairman of the Association's Committee on Legislative Activities, Samuel E Thompson, Kerrville, a former president of the Texas State Medical Association and Holman Taylor, secretary of the state association. Drs Leland Thompson and Taylor addressed a similar meeting in Houston in September under the auspices of the Harris County Medical Society.

### WASHINGTON

**Hospital News**—A thirty-two bed hospital for the treatment of Buerger's disease has been opened at Soap Lake according to *Northwest Medicine*. It was reported that the hospital has applications from 900 prospective patients.

**Society News**—Dr Brien T King, Seattle addressed the King County Medical Society, Seattle December 19 on 'A New and Function-Restoring Operation for the Relief of Bilateral Recurrent Nerve Paralysis' and Dr Ralph H Loe on 'Tumors of the Sacrococcygeal Region'. Drs Percy F Guy and Glenn S Usher of the state department of health, Seattle addressed the Cowlitz County Medical Society Longview, November 16 on causes and prevention of maternal deaths and on venereal disease control. Drs Joseph Irving Tuell, Seattle, and Melvin F Fuller, Aberdeen addressed the Grays Harbor County Medical Society, Aberdeen, November 16, on subdeltoid bursitis and treatment of pneumonia with sulfanilamide. Dr Louis P Gambee, Portland Ore, addressed the Walla Walla Valley Medical Society, Walla Walla, December 8 on intestinal obstruction due to recurrent volvulus of the sigmoid. A symposium on lobar pneumonia was presented before the Spokane County Medical Society, Spokane, December 8, by Drs George H Anderson, James D Edgar, Milo T Harris and Donald A Palmer.

### WISCONSIN

**Society News**—Dr Elmer L Sevringhaus, Madison, addressed the Dane County Medical Society, Madison November 10 on 'Pituitary Therapy in General Practice'. Dr Eben J Carey, Milwaukee, addressed a meeting of the Columbia-Marquette-Adams County Medical Society and its auxiliary with dentists, lawyers and pharmacists of the three counties in Portage November 9, his subject was 'Relation Between Medicine and the Public'. At a meeting of the Eau Claire-Dunn-Pepin County Medical Society November 28 Dr Robert P Montgomery, Milwaukee, spoke on 'Low Back Pain and Sciatica' and Mr C W Kroening of the Employers' Mutual Insurance Company Wausau on 'Wisconsin Hospitals and Medical Payment Plan' and 'Open Panel Agreement with Wisconsin Workmen's Compensation Carriers'. At a meeting of the Green Lake-Waushara Counties Medical Society

Berlin, November 21, the speakers were Drs William J Bleckwenn, Madison on "Diagnosis and Treatment of Head Injuries," John T F Gallagher, "Subacromial Bursitis," and George H Ewell, "Urological Problems of General Interest" —Dr Philip H Kreuscher, Chicago, addressed the Rock County Medical Society, Janesville November 22 on 'Injuries and Diseases Involving the Lower Part of the Spine and Sacro-Iliac Joints'

### GENERAL

**Special Society Elections**—Dr Arthur T McCormick, Louisville, Ky, was named president elect of the Southern Medical Association at the annual meeting in Oklahoma City in November and Dr Walter E Vest, Huntington, W Va was installed as president Drs Henry H Turner, Oklahoma City, and William Hibbitts, Texas, were elected vice presidents The 1939 meeting will be held in Memphis, Tenn Dr Vest appointed Drs Robert M Anderson, Shawnee, Okla, William H Anderson, Booneville, Miss, and Lucien A LeDoux, New Orleans, to the council of the association to succeed respectively Drs Willis K West, Oklahoma City, Harvey F Garrison Jackson, Miss, and Arthur A Herold, Shreveport, La

**Casselberry Prize to Be Awarded**—The American Laryngological Association announces that the sum of \$500 has accumulated from the Casselberry Fund and will be awarded in part or as a whole as a prize, a decoration or for the expense of original investigation or research in the art and science of laryngology and rhinology Theses or reports of work done must be in the hands of the secretary Dr James A Babbitt, 1912 Spruce Street, Philadelphia, before February 1 Any further information may be obtained from Dr Babbitt

**Bequests and Donations**—The following bequests and donations have recently been announced

Rivercrest Preventorium, Mont Clare, Pa, of the Kensington Dispensary for the Treatment of Tuberculosis \$15,000 by the will of the late Amos Bird, Jr, retired ship captain

St Vincent's Hospital \$20,000 New York Foundling Hospital and St Ann's Maternity Hospital, all of New York \$5,000 each by the will of Mrs Eleanor Iselin Kane

New York Medical College, Flower and Fifth Avenue hospitals, New York \$20,000 to endow a bed for needy American artist musicians by the American Criterion Society

The Doernbecher Hospital and Shriners' Hospital for Crippled Children, Portland, Ore, each one third of a \$25,000 estate left by Fred A Allen

Montefiore, Hebrew Beth Israel hospitals and the Hospital for Joint Diseases, New York \$11,645 each by the will of the late Betsy Dinkelman

Englewood Hospital, Englewood, N J \$10,000 by the will of the late Frederick Lyon

**Medical Director Appointed**—Dr John Warren Bell, Lincoln, director of maternal and child health in the state department of health of Nebraska, has been appointed medical director of the National Society for the Prevention of Blindness With this addition to the staff the society plans more extensive cooperation with the medical profession and local, state and national health officers and associations Dr Bell graduated from the University of Minnesota Medical School, Minneapolis, in 1916 Before going to Nebraska he was director of the division of maternal and child health in Cattaraugus County in New York

**Warning of Swindler**—California physicians have recently complained that a man using the name Andrew Dolte has been posing as a representative of the F A Davis Company, medical publishers of Philadelphia, the company reports The man has taken orders for medical books, collected for them and failed to deliver the books In many instances he has induced physicians to give him books from their libraries and has not delivered other books in exchange as promised This impostor is about 45 years old, 5 feet 11 inches tall, clean shaven and has a receding chin It is believed that he will attempt to continue operations in the Western and Southern states Any information should be referred to local Better Business Bureaus or to the bureau in San Francisco

**Orthoptic Council Organized**—A group of ophthalmologists representing the American Ophthalmological Society, the Section on Ophthalmology of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology met in Washington October 11 and organized the American Orthoptic Council Dr Le Grand H Hardy, New York, was elected president of the new council Dr Derrick T Vail, Jr, Cincinnati, vice president and Dr Edwin B Dunphy, Boston, secretary The group adopted resolutions suggesting that the national societies through the American Orthoptic Council should take over training of technicians for this work and should establish a central training station for

them It was planned that examinations would be held at least once a year, with certificates of proficiency for successful candidates A syllabus for student orthoptic technicians is being prepared

### CANADA

**Typhoid in British Columbia**—Twenty-six known cases and four suspected cases of typhoid occurred in Merritt, B C, in October Investigation of the outbreak indicated that the disease was probably transmitted through raw milk

**Personal**—Sir Frederick G Bunting, Toronto, delivered the W E Dixon Memorial Lecture of the Royal Society of Medicine, London, at a meeting of the section of therapeutics and pharmacology recently His subject was 'The Immunologic Aspect of the Tumor Problem' —Dr Alexander R Munroe, Edmonton, Alta, has resigned as professor of surgery at the University of Alberta Dr William Fulton Gillespie, associate professor of surgery, succeeded him

**Cancer Control Society**—After several months of organizational work, the Canadian Society for the Control of Cancer has been chartered and provincial branches are being formed Dr Cecil C Ross, formerly instructor in surgery at the University of Western Ontario, London, has been appointed executive secretary and headquarters have been established at 43 St George Street, Toronto, in an office donated by the University of Toronto Pending the first meeting of the grand council, to which each province is to elect one medical and one lay member, the national board of directors is composed of Drs John S McEachern, Calgary, Alta, president, George S Young, William E Gallie and Thomas C Routley, all of Toronto, Mr E S Macfarlane, Mr F K Morrow and Mr H Napier Moore, all of Toronto The new society is sponsored by the Canadian Medical Association and has the endorsement of the trustees of the King George V Silver Jubilee Cancer Fund for Canada Within the dominion medical association a department of cancer control is being organized to act for the medical profession in advancing the aims of the cancer society These aims are enlistment of the Canadian public, ensuring that the facts known at present are intelligently applied, and educating all men and women to realize that in many cases cancer can be cured if treatments are started in time

### FOREIGN

**Personal**—Dr Julius de Daranyi, director of the Hygiene Institute of the Royal Hungarian Peter Pazmany University of Budapest, has been made president of the Hungarian Committee on Postgraduate Medical Education

**Society News**—Dr Warren H Lewis, of the department of embryology at the Carnegie Institution of Washington and Johns Hopkins University School of Medicine, Baltimore, was elected president of the International Congress for Experimental Cytology at the 1938 meeting in Zurich The next congress will be in Stockholm in August 1940 —The sixth Australasian Medical Congress will meet in Perth, Western Australia, in August 1940 The main theme of the congress will be 'Rheumatic and Allied Disorders'

**Tuberculosis Prize Awarded**—The Leon Bernard Memorial Prize, recently established to honor the late Dr Bernard who for fourteen years was secretary general of the international Union Against Tuberculosis was awarded to Dr Karl Fischel, at one time on the staff of the Will Rogers Memorial Hospital, Saranac Lake, N Y, Dr E Arnold of France and Dr John B McDougall of Great Britain, according to the Bulletin of the National Tuberculosis Association The award was announced at a meeting of the executive committee and the council of the union in Paris

**Congresses on Ophthalmology**—The International Association for the Prevention of Blindness will meet in London April 19 preceding the annual congress of the Ophthalmological Society of the United Kingdom Use of the Crede method for the prevention of ophthalmia neonatorum will be the subject for discussion at the international meeting Speakers will include Dr Conrad Berens, New York, Dr Arthur H H Sinclair, Edinburgh, Prof F Terrien, Paris, Prof V Szily, Munich, Prof Luigi Maggiora, Genoa, Prof Vasquez Barriere, Montevideo, Dr Rowland P Wilson, Cairo, Egypt, and Dr John D M Cardell, London This association may be addressed at 66 Boulevard Saint-Michel, Paris VI Also on April 19 the International Organization Against Trachoma will hold a meeting to discuss the incidence and types of trachoma in various parts of the world The speakers will be Drs Harry S Gradle, Chicago, Dr Francis J Lavery, Dublin and Mr Arnold Sorsby, London The address of this organization is 33 Welbeck Street, London W 1

#### The Cancer Bill

In moving the second reading of the cancer bill in the House of Commons, the minister of health, Mr Elliot, said that it was urgently necessary to bring facilities for the treatment of cancer within the range of every person. The success of radium and x-rays depended on treatment at an early stage. Ample facilities for early diagnosis and adequate treatment were necessary but at present were lacking. Cancer was increasing and had become second on the list of fatal diseases in this country. There were 74,000 deaths from it in Great Britain in 1937. Of all deaths during the working period of life (between the ages of 15 and 65), 17 per cent were due to cancer. About 10,000 deaths occurred under the age of 50. Cancer was not, as was sometimes thought, an old person's disease. Its annual death rate per million of the population of Great Britain was 835 for 1901 and 1,624 for 1937. Thus the death rate had nearly doubled in a generation, in striking contrast to that of other diseases, for which there had been a steady fall. There had been much discussion as to whether the figures represented a real increase of cancer. The general opinion was that much of the increase was explicable in other ways, such as increased longevity and more accurate diagnosis. For cancer of the more accessible organs, lip, jaw and skin, the mortality was declining at almost every age. This was probably due in part to treatment.

From inquiries conducted by the ministry it had been estimated that in this country there were in 1937 more than 100,000 persons suffering from cancer. Of these about 10 per cent had the disease in organs for which treatment had not hitherto been practicable. Fifty per cent of the cancers were susceptible to treatment by surgical intervention alone, but only if diagnosed early. This group included cancers of the stomach and intestine, which accounted for the largest number of deaths. There remained 40,000 persons who suffered from easily accessible cancers. For these surgical intervention, often combined with radiation, or radiation alone, was effective, especially in the early stage. Even when the disease was too advanced for cure, alleviation could be obtained from radiation. Even in some apparently hopeless cases cure, judged by five years' freedom from symptoms, was obtained.

For internal cancers the problem was not so much treatment as diagnosis. Many patients applied for treatment too late. Fearing that they were suffering from cancer, which they regarded as incurable, they delayed seeking advice. The bill was designed to combat the bogey of incurability. It would secure that no one, wherever domiciled, who was suffering or was suspected by his physician to be suffering from cancer would be out of the reach of the best advice and treatment. Every one would be able to obtain admission to an appropriate hospital whether for further examination or for treatment. The proposals would be financed by local authorities in conjunction with the government, which was prepared to make a grant of \$2,500,000. It was estimated that 1,000 new hospital beds and between 300 and 350 consultation centers would be required. The bill prohibited advertisements of "cancer cures," which have already been banished voluntarily by reputable journals. After some criticism of details the second reading of the bill was carried by a majority.

#### Spinal Epidural Suppuration

Spinal epidural suppuration is a rare condition which is often unrecognized, and the scanty literature for the most part consists of reports of single cases. It appears, however, not

to be so rare as the records show. The Birmingham surgeon Mr F. A. R. Stammers has been able to record in the *British Journal of Surgery* seven cases which he has observed since 1932. The usual mode of infection is extension from contiguous structures. The condition was secondary in three of his cases to staphylococcal osteomyelitis of laminae, in one to tuberculous disease of a lamina, in one to a suppurating tubulodermoid passing through a spina bifida and in one to a suppurating sacrococcygeal sinus. In the seventh case it was hematogenous. Dandy (*Archives of Surgery* 13:477 [Oct] 1926) said that in some cases it results from spread along adjacent lymphatics and mentions two cases in which it followed a carbuncle in the dorsal region. In two of Stammers' cases it was localized and produced signs indistinguishable from those of neoplasm within the spinal canal, pain, sensory and motor changes, and conditions in the cerebrospinal fluid. There was diffuse suppuration in the other five cases, with certain features in common. Pain in the back was the first symptom. The spine became stiff, and this proved to be a matter of absolute limitation of flexion while hyperextension was still free and painless, a point of distinction from tuberculosis of the spine. In all cases this stiffness slowly or rapidly involved more and more of the spine, in some cases neck rigidity and even head retraction developed. Another common feature was pyrexia. Stammers holds that the combination in a young patient of pain in the back, limitation of flexion tending to involve higher and higher levels with free hyperextension, and pyrexia means ascending spinal meningitis secondary to infection within the spinal canal but outside the dura. Osteomyelitis is the commonest cause, but its diagnosis in the spine is particularly difficult. Lumbar puncture carries grave risks, though useful information might be obtained by inserting the needle only into the epidural space. One patient presented slight edema over the dorsolumbar part of the spine. If the patient is very ill with a high temperature and great pain, and if in addition there is a tender spinal zone or slight edema, the cause is osteomyelitis of a vertebra. Immediate operation is then necessary not only to relieve toxemia but because paraplegia may occur at any moment and develop so rapidly (within twenty-four hours) and clear up so slowly, or not at all, in spite of drainage of the abscess that its genesis must be vascular.

#### The Evacuation of Children in Time of War

In a previous letter to THE JOURNAL it was stated that during the recent international crisis the government was prepared to evacuate 500,000 children from London in one day, because of the danger of air attacks. An evacuation division has been set up at the ministry of health, and, as children are so much concerned, officers of the board of education will serve. In addition, an advisory committee representing local education authorities and teachers is to be set up. Plans are to be worked out for the evacuation of children, school by school, accompanied by their teachers, so that their education can continue. Arrangements will also be made for the evacuation of children under school age accompanied by their mothers if they elect to go. The billing will be arranged to insure as far as possible that children will be received into homes where their presence will be welcome.

#### Drug Addiction in Great Britain

The government report to the League of Nations on traffic in opium and other dangerous drugs for 1937 states that addiction to narcotic drugs is not prevalent in Great Britain. The known addicts number 620, 300 men and 320 women. It is noteworthy that of these 132 are physicians, five are pharmacists, two are veterinary surgeons and one is a dentist. Thus contact with drugs appears to be an important factor in addiction. In 72 per cent of the cases the drug taken is morphine,

in 17 per cent heroin and in 85 per cent cocaine. There is no evidence of organized illicit traffic in this country. The thirty-nine prosecutions under the dangerous drug acts were in all cases for breaches of the acts or regulations and not for trafficking. The government department dealing with drugs cooperated successfully with Canada, Egypt, the United States, the Netherlands and France in checking the traffic abroad. The possession and use of opium prepared for smoking are totally prohibited in Great Britain, and when the drug in this form is seized it is confiscated and destroyed.

### The British Congress of Obstetrics and Gynecology

The eleventh British Congress of Obstetrics and Gynecology will be held at Edinburgh April 4-6. The chief subject for discussion will be pain in labor and methods of alleviation. It will be introduced by Prof. Chassar Moir of Oxford and Dr. John Sturrock of Edinburgh. The official guests of the congress will be Professor Wagner of Berlin and Dr. S. R. Meaker of Boston. Other subjects to be dealt with are genital hypoplasia, dysmenorrhea, tubal infection, hyperemesis gravidarum, results of pregnancy toxemia, trichomonas infection, male sterility, habitual abortion and myometrial activity. A visit will be paid to the department of animal genetics under the direction of Prof. F. A. E. Crew. Those who desire to exhibit should communicate with the local secretary of the congress, Dr. Chalmers Fahim, 7 Chester Street, Edinburgh 3.

### BERLIN

(From Our Regular Correspondent)

Dec 5, 1938

### Cancer and the Vitamin Economy

Prof. Erich Schneider of the University Surgical Clinic, Freiburg-in-Breisgau, has in the last five years investigated cancer and the vitamin economy. A survey of the five year survival of cancer patients shows how small is the proportion for whom radical operation is the most feasible therapeutic procedure. The total number of cancer patients in the last ten years was 1,425. Of these, 676 patients submitted to operative treatment, namely, 483 underwent radical operations

#### *Survival of Cancer Patients Who Underwent Radical Operation*

Diagnosis of Carcinoma According to Site	Number of Patients	Percentage Alive Five Years After Operation
Breast	171	24.2
Skin	95	39.2
Stomach	61	7
Rectum	46	11.8
Lower lip	38	26.4
Parotid	14	54.5
Lung	12	11.1
Penis	9	33.3
Bladder	10	0
Upper jaw	8	0
Gallbladder	4	0
Testis	2	0

and 193 underwent palliative operations. Of the last-mentioned group, only three patients with cancer of the stomach were alive five years after operation regardless of whether roentgen irradiation was done. The table contains data on the five year survival of patients who underwent radical operation.

Earlier investigators, particularly Gordonoff and Ludwig at Berne, demonstrated a general inhibition in the growth of fibroblasts and cancer cells in patients presenting avitaminoses, and this was most remarkable if the deficiency was in vitamins A and B<sub>1</sub>. An excess of these vitamins led on the contrary to a notable increase in growth of the mentioned cells, whereas vitamins C, B and E exerted no measurable effect. From this one may infer that curtailment of the vitamin supply

of the patient's dietary is a therapeutic indication. However, clinical examinations of cachectic cancer patients elicit evidence of the genesis and development of a strongly marked hypovitaminosis combined with classic manifestations. With the advance of cancer the vitamin A values of the body serums are observed to decline, the finding may even be completely negative. This disturbance is accompanied in about 20 per cent of the cases by so called pathologic excretion of vitamin A in the urine. A deficiency of this sort is not based on the size of the cancerous tumor and is likewise independent of metastasis and of the cholesterol values. Much more frequently one can prove that it originates solely through the concomitant infection in the decomposing tumor, with its toxic effect on the liver and hepatic reticulo endothelial system. Correspondingly, after therapeutic exhibition of vitamin A there is of course no observable deleterious reaction in the sense of an increased development of the tumor. With respect to vitamin C it was found that after the usual tolerance tests abnormally high deficits were demonstrable. Impairment of the blood-kidney barrier for permeability of vitamin C may be excluded. The kindred assumption of a pathologically increased oxidative capacity of the carcinomatous plasma as a cause of the diminished secretion was not established. Rather the oxidation capacity was reduced by about 30 per cent. Furthermore, it was demonstrated with Jensen's sarcoma of rats that a possible increase in the liver glycogen value by exhibition of vitamin C was manifested in the tumor animals. However, no clearly life-prolonging effect of vitamin C therapy was observed. This utilization of vitamin C in the process of glycogen synthesis explains the high vitamin requirement and the lack of excretion in the urine as well as the absence of scorbutic manifestations. The phenomena may be interpreted as defense mechanisms of the organism.

### Schools for the Hard of Hearing

The National Health Bureau has published a report by Dr. Dornedden on schools for the hard of hearing in Germany. Although schools for the blind and for the severely deaf have been nationally regulated since 1911, uniformity of regulation does not exist with regard to education of children who are hard of hearing. Only a few cities have created special schools and classes for pupils with defective hearing in order to relieve the regular classes of this additional teaching burden. About 1,600 pupils with defective hearing (765 boys and 658 girls) attend the special schools. The limits within which the children can follow instruction in the classroom have been set at 0.5 meter for the whispering voice and from 3 to 4 meters for the ordinary conversational tone. Incontestable determination of the proportion of children whose hearing is defective but who cannot be actually classified as deaf has not been made, but the number may be estimated at 5 per thousand of all school children, namely about 40,000 within the German Reich. The mentioned 1,600 accommodations take care of scarcely 4 per cent of the need, exclusive of Austria.

The common elementary school is in no position to recognize and utilize the educative capability of these children, who can immediately be placed on the road to ampler development if they are offered a better type of instruction. Such instruction will compensate for present poor performances, which are due to limited educational facilities. Institutions for deaf-mutes are unsuitable for children who are merely hard of hearing. It is therefore recommended that such children be placed in schools designed especially for them. In such schools each class ought not to contain more than fifteen pupils. Each school would thus have a pupil population of about sixty, and this means one school to each 12,000 children. The training of teachers is similar to the training of teachers of deaf-mutes. Fairly gifted pupils can thus receive a general education suffi-

cient for pursuit of a practical occupation, and especially talented pupils will be able to receive more advanced instruction. Training in handicrafts and draftsmanship is especially to be promoted.

### Poliomyelitis in 1938

Dr Gantenberg reports to the Berlin Medical Society eighty cases of poliomyelitis observed during the last year. The 1938 epidemic was characterized by severe involvement of the meninges, not merely as meningism but rather as true spinal meningitis, with much more pronounced painfulness of the musculature and the nerve trunks. At the outset many catarrhal manifestations in the upper respiratory passages were observed, frequently together with muscular pain of the rheumatic type and ischialgia. The cerebrospinal fluid always gave positive Nonne-Apelt and Pandy reactions and showed a great increase in cells, particularly lymphocytes. In some cases the sugar content was increased, but in a few it was lowered. On the basis of pathologic-anatomic observations, this year's prevalent form of poliomyelitis could be designated true meningo-encephalomyelitis.

### A Museum of Pharmacy

The newly founded Museum of Pharmacy has been opened at Munich. It was called into being by a gift made in March 1937. Already its exhibits, which are to be extensively added to, offer an impressive record of the cultural history of the apothecary's profession. In southern Germany in particular, with its ripe old culture, furnishings of old time apothecary shops are frequently found which possess an artistic value. The museum's collection of drugs represents an initial attempt at a historical exhibit of the kind. The entire collection from the private museum of the historian of pharmacy Dr Ferchl of Mittenwald, Upper Bavaria, was obtained directly from the possession of German apothecary shops.

### Prof Otfried Forster Retires

Having reached the age of 65, Prof Otfried Forster has retired from the chair of neurology and psychiatry at Breslau University. Through his basic research in anatomy and physiology as well as in the pathology of the nervous system, Forster has gained for himself an illustrious name. Neurosurgery likewise is much in his debt. The intradural resection of the dorsal nerve roots, for abolishment of spastic paralysis and tabetic crises, is known as Forster's operation; it was done by him as early as 1909. In 1935 Forster was awarded a British prize, the Jackson gold medal.

### AUSTRALIA

(From Our Regular Correspondent)

Dec 7, 1938

### Health Insurance Difficulties

There is reason to doubt that the National Health and Pensions Insurance Act placed on the statute books several months ago in the face of strong opposition and after one of the longest parliamentary debates in Australian history, will ever be implemented. No agreement has yet been reached between the federal government and members of the British Medical Association in Australia. This difficulty has been responsible for the official postponement of operations originally planned to commence Jan 1, 1939. The royal commission set up to investigate the question of fees payable to practitioners working under the scheme has not yet reached a decision but is expected to report before the end of the year. This commission, however, is dealing only with financial aspects of the case, and, whatever its conclusions may be, it is doubtful that cooperation between the government and the profession will ensue, for medical opinion is that more than finance is involved

in the provision of a satisfactory national medical service. It is felt that medical service should at least be complete, including the insured man's wife and family and providing all forms of medical treatment. The estimated cost per person of a complete medical service has been drawn up for Australia and compared with similar figures for British Columbia and New Zealand. It has been estimated that in Australia each breadwinner has an average of one dependent. If each breadwinner pays about twice the cost per person, a complete "cover" is given to every member of the community and the single breadwinner helps to carry the load of the married man with a family.

Indicative of the general feeling toward the government scheme is a resolution carried in Melbourne by the federal council of the British Medical Association. Under this motion, members of the association are asked to pledge themselves not to accept service under the act unless 70 per cent of the members agree to do so. It is pointed out that signatories are not refusing to accept service but are agreeing to abide by a decision of the majority. The New South Wales branch of the British Medical Association is confident that 90 per cent of its members will sign the resolution, and one Melbourne doctor has distributed 3,500 eight page anti-insurance pamphlets to members of the British Medical Association all over

### Cost per Person (Approximate) of Complete Medical Service

	British Columbia		New Zealand		Australia	
	Shil- lings	Pence	Shil- lings	Pence	Shil- lings	Pence
General practitioner service	13	7	15	0	16	0
Maternity service		10				
Special service	4	0	2	0	3	0
Dental service	2	0	7	6	5	0

Reserve fund	4	0	3	9¼	4	0
	2 10	0	2 15	0	2 15	0

Australia. A disadvantage of the present scheme is that it is intimately bound up with pension payments and cash benefits. It is felt that the profession can cooperate fully only in a plan for health insurance which is entirely separated from these other measures. Suggested alternatives to the government scheme are schemes either controlled by the British Medical Association or in conjunction with friendly societies.

During the past several months the British Medical Association in Australia has collected, at great expense of time and money, a great deal of information regarding medical practice in Australia and possible effects of national insurance. Masses of data are now available which were unobtainable before the drafting of the bill, at the time when members had to negotiate with the government's experts. They were then unable to substantiate their claims and had to accept as correct figures and statements presented to them by the government. Now, however, the association is provided with sufficient information to enable it to discuss health insurance on an equal footing with the government.

Apart from the opposition of the medical profession, the government is meeting severe criticism from other quarters. First, from a strong federal labor opposition, second, from a section of employers who regard with misgiving the extra cost that they will have to carry as contributors to the scheme on behalf of their employees, third, from a body of rural opinion which voices the grievances of small farmers who will be required to pay contributions for persons they employ but

who will not themselves, as self employing persons, be eligible to become insured, and, finally from the existing friendly societies

### Royal Australasian College of Physicians

The inauguration of the Royal Australasian College of Physicians, which took place December 13 and succeeding days, was an important event in the medical history of Australia and New Zealand. It is fitting that the ceremony was held in the great hall of the University of Sydney thereby demonstrating the happy union in spirit of this new body with the older academic institutions. The new college like its companion body the Royal Australasian College of Surgeons will serve to set and maintain a high standard in its special form of practice, although it is not a licensing body. Its constitution has been modeled on that of the Royal College of Physicians of London to the extent that it admits two grades of medical practitioners—members and fellows, with the powers of government vested chiefly in the fellows. The object which influenced the founders to recognize the grades of member and fellow was to encourage medical graduates to become members without regard to the form of practice they follow, thus allowing them the privileges of union with the college whether they are engaged in academic work, in public administrative medicine or in general practice including the ordinary run of surgical and obstetric work. From the fellows, however, will be demanded a higher standard of achievement and a greater restriction of work, as they will be engaged in consulting practice as physicians and in medical teaching or will be following the auxiliary branches of scientific medicine. It is already a policy of the college to encourage physiologists, pathologists, dermatologists and radiologists to enter its ranks, and among its foundation fellows are representatives of these branches of the profession.

Eventually, fellows will all pass through the preliminary door of membership and will be promoted to the rank of fellow on attainment of professional eminence. Membership is gained by examination only, but it is provided in the regulations that candidates possessing a recognized higher medical qualification will be excused from a written test, a privilege that may also be extended during the next five years to practitioners of not less than fifteen years' experience. This recognition, on the one hand, of the value of qualifications such as the higher degrees conferred by universities and, on the other, of the practical wisdom attained by general practitioners in caring for the health of the public meets with general appeal, and the profession in Australia looks forward with optimism to the working of this leaven in the medical community.

### The Hospital Problem

The determination of the Nurses Wages Board in Victoria to introduce a fifty hour week is a welcome step toward reform, but the decision has presented a new problem to public hospitals. It has been disclosed that the nursing staffs of the public hospitals will have to be increased by about 30 per cent in order that the new ruling may be observed and concern is expressed at the fact that already there is a shortage of nurses, with little prospect of meeting the unexpected demand. Furthermore, the increase in salaries together with the need for additional buildings in which to accommodate the extra staff may place some of the hospitals in an embarrassing financial position.

The problem of the shortage of nurses is a real one in Australia. It has been suggested that it may be overcome by a reduction of the training course from three to two years, the provision of better living conditions for nurses in hospitals and the employment of more fully trained nurses instead of trainees in paying portions of hospitals. Trainees are doing so much of the work in hospitals that positions for trained nurses are interfered with. To meet the situation not only

must nurses be brought into the profession, they must be kept there. But it will take more than a mere shortening of hours to make nursing attractive. More far-reaching and expensive remedies are necessary. Realization of this fact and of the consequent rise in the cost of adequate medical care is but one more argument in favor of greater activity in the field of preventive and constructive medicine.

### Plans to Overcome Malnutrition

At a meeting of the National Health and Medical Research Council, arrangements were made to implement the recommendations of the Commonwealth Advisory Council on Nutrition to improve the diet of the people in this country. They include the appointment of a committee to study the correction of faulty diet and to investigate and rectify special nutritional disorders. The official representative of each state will recommend to his government the immediate formation of a state committee to undertake the improvement of the nutritional status of the people as an immediate social obligation.

## Marriages

ELTON S. OSBORNE JR., Nichols, Fla., to Miss Marie Wilson Willis of Monticello, Fla., in Jacksonville, July 30, 1938.

ZACK DOWDY OWENS Elizabeth City, N. C. to Miss Martha Anderson of Houston, Minn., at Baltimore, Oct. 16, 1938.

CLAUDE C. BLACKWELL, Birmingham, Ala. to Miss Mary Latham Rowland in Washington, N. C., Nov. 5, 1938.

TRUGOTT J. G. BLOEDEL Thief River Falls, Minn., to Miss Marion Bernice Long of Minneapolis, Nov. 9, 1938.

FREDRICK A. WIES New Haven, Conn., to Miss Vivian Wilbour Nelson of Manchester, N. H., Oct. 4, 1938.

EDGAR WILLIAM WARREN II, New Haven, Conn., to Miss Helen A. Mead of New York, Nov. 19, 1938.

HARRY JUSTICE WARTHEN JR., to Miss Martha Winston Alsop, both of Richmond, Va., Sept. 1, 1938.

LE ROY HAMILTON WARDNER to Miss Carolyn W. Potter, both of Saranac Lake N. Y., Aug. 27, 1938.

CHARLES LLOYD LAWSON Acmar, Ala., to Dr. NETTIE MARIE BLACK of Columbia, S. C., Nov. 30, 1938.

HENRY THOMAS BALLANTINE JR., Boston, to Miss Elizabeth E. Minter of Brookline, Mass., recently.

WILLIAM STURGES PARKER Merion Station, Pa., to Miss Anita Woodruff Jones, Sept. 10, 1938.

ROY A. HOFFMAN, Minneapolis to Miss Lolita B. Wilkinson of Cloquet, Minn., Oct. 16, 1938.

ENNION SKELTON WILLIAMS to Miss Ann Hill Brown, both of Richmond, Va., Dec. 2, 1938.

JOHN KILGO WEBB to Miss Marjorie Barr O'Steen, both of Greenville, S. C., Oct. 8, 1938.

GUSTAVE FREEMAN, Chicago, to Miss Elizabeth G. Hulse of Monroe, N. Y., Dec. 29, 1938.

LONDON TIMBERLAKE to Miss Mary Perry, both of Birmingham, Ala., Oct. 5, 1938.

G. HOWARD GOWEN to Miss Ruth Cogdal, both of Champaign, Ill., in October 1938.

EDWARD B. WEINMAN, Ann Arbor, Mich., to Miss Evel Allender in October 1938.

HAROLD M. GOLDEN to Mrs. Myrtle Riley, both of Los Angeles, Oct. 29, 1938.

ALBERT F. LEE Durham, N. C., to Miss Frances Halliday of Seattle, Nov. 2, 1938.

H. KERVIT BRASK, Nashville, Tenn., to Miss Roberta Barbara White recently.

JOHN E. SIEDLINSKI to Miss Charlotte A. Savickis, both of Chicago, August 28.

PATRICK U. DE VITO to Miss Teresa Riggio, both of Brooklyn, Dec. 4, 1938.

SAMUEL NORWOOD to Miss Miriam Cary, both of Chicago, Sept. 17, 1938.

## Deaths

**Dr. Hugh Talbot Patrick** ☉ eminent neurologist, died in Chicago, January 5, of carcinoma of the stomach. Dr. Patrick was born in New Philadelphia, Ohio, May 11, 1860. After his preliminary education in the University of Worcester (1878-1880), he received the degree of doctor of medicine from Bellevue Hospital Medical College of New York University in 1884. He studied nervous and mental disease abroad from 1891 to 1894 and then returned to Chicago to take up the practice of neurology. In 1896 he married Fanny E. Gary, daughter of Judge Joseph E. Gary. In 1896 also he became professor of nervous and mental disease in the Chicago Polyclinic. He became assistant professor of nervous disease in Northwestern University in 1894, later clinical professor, and subsequently emeritus professor of nervous disease. He had been from time to time attending or consulting neurologist to the Wesley, Passavant, Polyclinic, Henriotin Memorial and St. Anthony's Hospital, as well as to the Illinois Charitable Eye and Ear Infirmary and the Illinois Eastern Hospital for the Insane. His eminence as a practitioner in his special field was recognized by election to the presidency of the American Neurological Association and the Chicago Neurological Society. He was also corresponding member of the Société neurologique de Paris. During the World War he served as consultant neurologist and saw service in several of the larger camps in the United States.

To the American Medical Association Dr. Patrick contributed of his efforts as a delegate from Illinois in 1912 to the House of Delegates, and again in 1919-1920 as a delegate from the Section on Nervous and Mental Diseases. He served in the same year as chairman of the Reference Committee on Sections and Section Work. He also served as secretary of the Section on Neurology and Medical Jurisprudence from 1897 to 1899, and as chairman of the section 1899-1900.

Dr. Patrick gave especially of his services in the foundation of the *Archives of Neurology and Psychiatry*, making it without doubt the leading publication in its field in the world. He was active in organizing support for such a periodical and became its first editor. In November 1936 a special issue of the *Archives of Neurology and Psychiatry* was dedicated to him. It contained, in addition to notes of appreciation by Drs. Peter Bassoe, Bernard Sachs and Prof. Georges Guillain of Paris, contributions on neurologic topics by these writers and by many others who were from time to time associated with Dr. Patrick in his work. As editor of the *Archives of Neurology and Psychiatry* he was instrumental in making it reflect constantly the progress of American medicine in the fields of neurology and psychiatry.

His own contributions to the advancement of his specialty included articles on arteriosclerosis of the nervous system, chronic progressive hemiplegia, the motor neuron in practical diagnosis, the proper care and treatment of the patient with epilepsy, syphilis of the nervous system, and the factor of fear in nervous diseases. As he grew older he developed special interest in biographies and the historical aspects of neurology.

The death of Dr. Hugh T. Patrick is mourned by innumerable physicians and laymen who admired his facile mind, his wit and his faithful friendship.

**T. Wingate Todd**, Cleveland, Victoria University of Manchester Medical School, England, 1907 and F.R.C.S., England, 1911, member of the Ohio State Medical Association and the American Association of Anatomists, demonstrator in anatomy at the Manchester University, 1907-1910, and in 1910 lecturer

on anatomy and clinical anatomy, Henry Willson Payne professor of anatomy at the Western Reserve University School of Medicine and director of the Hamann Museum of Anthropology, chairman of the Brush Foundation, director of research, Developmental Health Inquiry of Associated Foundations, served with the Royal Canadian Army Medical Corps, corresponding member of the Société d'anthropologie de Paris, Académie royale de médecine de Belgique, author of "Clinical Anatomy of the Gastrointestinal Tract," "An Introduction to Mammalian Dentition," "Behavior Patterns of the Alimentary Tract" and "Atlas of Skeletal Maturation", aged 53, died, Dec. 28, 1938, of coronary arteriosclerosis and thrombosis.

**Herbert U. Williams**, Buffalo, University of Buffalo School of Medicine, 1889, University of Pennsylvania Department of Medicine, Philadelphia, 1891, since 1934 professor of pathology and bacteriology emeritus at the University of Buffalo School of Medicine and dent, 1912-1915, past president of the Buffalo Academy of Medicine, member and past president of the American Association of Pathologists and Bacteriologists, member of the Association of American Physicians, honorary member of the Société de médecine d'Haiti, in 1913 member of the state board of medical examiners, formerly pathologist to the Buffalo General, Erie County and Buffalo City hospitals, author of "Manual of Bacteriology," 1898 and monographs on origin of syphilis, paleopathology and mummies, aged 72, died Dec. 8, 1938, of pulmonary edema.

**Frederick William Johnson** ☉ Newton, Mass., Harvard University Medical School, Boston 1881, fellow of the American College of Surgeons, at one time professor of clinical gynecology, Tufts College Medical School, Boston, served in various capacities and at various times on the staffs of the Massachusetts Women's Hospital, Carver Hospital, St. Mary's Infant Asylum and St. Elizabeth's Hospital, Boston, Jordan Hospital, Plymouth, Sturdy Memorial Hospital, Attleboro, and the Elliot Hospital, Manchester, N. H., aged 85, died, Dec. 3, 1938, of aortic stenosis.

**Frederick L. Van Sickle** ☉ Harrisburg, Pa., Jefferson Medical College of Philadelphia, 1886, member of the House of Delegates of the American Medical Association in 1916-1917 and in 1923, past president and formerly executive secretary of the Medical Society of the State of Pennsylvania, past president of the American Academy of Medicine, formerly medical director of the Mid-Valley Hospital, Peckville, at one time editor of the *Atlantic Medical Journal*, now the *Pennsylvania Medical Journal*, aged 76, died, Oct. 9, 1938, of arteriosclerosis and myocarditis.

**John Raymond Hume**, New Orleans, State College of Physicians and Surgeons, Indianapolis, 1907, member of the Louisiana State Medical Society, professor of otolaryngology, Tulane University of Louisiana School of Medicine, member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otolological Society, for many years on the staff of the Eye, Ear, Nose and Throat Hospital, aged 55, died, Oct. 29, 1938, of coronary occlusion and hypertension.

**George Clowes Van Wart**, Fredericton, N. B., Canada, University of Pennsylvania Department of Medicine, Philadelphia, 1890, past president of the Medical Council of Canada and the Council of Physicians and Surgeons of New Brunswick, fellow of the American College of Surgeons, senior surgeon to the Victoria Public Hospital, aged 70, died, Oct. 1, 1938.

**William Rush Hockenberry**, Shippery Rock, Pa., Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1897, member of the Medical Society of the State of Pennsylvania, president of the board of trustees of the Shippery Rock State Teachers College, aged 71, died, Oct. 4, 1938, of chronic nephritis and arteriosclerosis.

HUGH TALBOT PATRICK, M.D., 1860-1939

**Moses Kleiner** • Denver, Yale University School of Medicine, New Haven, 1888, formerly associate professor of therapeutics, University of Colorado School of Medicine, on the staffs of the Mercy, St Anthony's and Beth Israel hospitals, aged 70, died, Dec 1 1938, in the New England Baptist Hospital Boston, of carcinoma of the pancreas

**Willis Bryant Moulton**, Portland, Maine, Medical School of Maine, Portland, 1883, member of the Maine Medical Association, formerly professor of ophthalmology and otology at the Bowdoin Medical School, for many years on the staff of the Maine General Hospital, aged 76, died Oct 8 1938, of arteriosclerosis and heart disease

**Siegfried Strauss**, Glenside, Pa, Hessische Ludwigs-Universität Medizinische Fakultät, Giesen, Hesse, Germany, 1911, member of the Medical Society of the State of Pennsylvania, served during the World War on the staff of the Abington (Pa) Hospital, aged 52, died, Oct 3, 1938, of coronary occlusion

**Alexander Stephens Garrett**, Weatherford, Texas, Atlanta (Ga) Medical College, 1890, formerly secretary of the Parker County Medical Society and past president of the Palo-Pinto County Medical Society, at one time city and county health officer, served as trustee of the public schools, aged 77, died, Oct 27 1938

**Malcolm Leal**, Colchester, Conn, New York Homeopathic Medical College, New York, 1879, at one time professor of theory and practice, New York Medical College and Hospital for Women, formerly consulting surgeon to the New York Ophthalmic Hospital, New York, aged 82, died, Oct 24, 1938, of acute myocarditis

**Edward Everard Adams**, Murphy, N C, Jefferson Medical College of Philadelphia, 1923, member of the Medical Society of the State of North Carolina secretary of the Cherokee County Medical Society, aged 39, died Nov 10, 1938, in St Mary's Hospital Knoxville, Tenn of pneumonia

**Walter Leon Knight** • Wewoka Okla, St Louis University School of Medicine St Louis, 1906, formerly secretary of the Seminole County Medical Society, for many years member of the board of education, medical director of a hospital bearing his name, aged 57, died Oct 18, 1938 of pneumonia

**Salvatore J Parlato** • Buffalo University of Buffalo School of Medicine 1920 served during the World War, aged 42, on the staffs of the Columbus Hospital Millard Fillmore Hospital and the Sisters Hospital, where he died, Oct 15, 1938, of injuries received in an automobile accident

**Noah Alexander Johnston**, Adamsville, Ala, University of Nashville (Tenn) Medical Department, 1907, member of the Medical Association of the State of Alabama, aged 62, died, Oct 13, 1938 in a hospital at Birmingham, of a self-inflicted bullet wound

**Frank Bowman Krimmel** • Erie, Pa, Hahnemann Medical College and Hospital of Philadelphia 1908 fellow of the American College of Surgeons on the staffs of the Hamot Hospital and St Vincent's Hospital, aged 53, died, Oct 3, 1938 of coronary thrombosis

**William L Kendall** • Enid Okla, Dallas (Texas) Medical College 1904, past president of the Garfield County Medical Society, at one time superintendent of the Northern Oklahoma Hospital, aged 61, died, Oct 12, 1938, of hemiplegia and hypertension

**Andrew J Hamilton**, Rison Ark, Arkansas Industrial University Medical Department Little Rock 1893, member of the Arkansas Medical Society, formerly city and county health officer, aged 74, died Oct 31 1938 of intestinal hemorrhage and hypertension

**Samuel Thompson Lindsay** • Rochester N Y, Harvard University Medical School Boston 1923, member of the American Society of Clinical Pathologists, on the staff of St Mary's Hospital, aged 54, died Oct 10, 1938 of acute gangrenous appendicitis

**Shepherd A Mullin**, West Chester Pa, Hahnemann Medical College of Philadelphia 1879, member of the Medical Society of the State of Pennsylvania, aged 81, on the staff of the Homeopathic Hospital where he died, Oct 16, 1938, of influenza

**Legan Henry Hobgood**, New Bedford Mass, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1921, member of the Massachusetts Medical Society, aged 45, died, Oct 27, 1938, of biliary cirrhosis

**William A Kearney**, Prospect, Va, University of Maryland School of Medicine Baltimore 1883, member of the Medical Society of Virginia, aged 83, died, Oct 17, 1938 in a hospital at Richmond of urinary calculi and bronchopneumonia

**Rush Oliver Lees**, Utica, N Y, Harvard University Medical School, Boston, 1897, member of the Medical Society of the State of New York, on the staff of St Luke's Hospital, aged 63, died, Oct 3, 1938, of coronary thrombosis

**George S Smith** • Liberal, Kan, Kansas City (Mo) Medical College, 1891, past president of the Meade County Medical Society, on the staff of the Epworth Hospital, aged 83, died, Oct 24, 1938, of chronic myocarditis and nephritis

**Frank Aylmer Woods**, Holyoke, Mass, Hahnemann Medical College and Hospital of Philadelphia, 1893, formerly member of the board of health, aged 67, died, Oct 17, 1938, in a hospital at Wellesley, Mass, of cirrhosis of the liver

**James Thomas C Affleck**, Sacramento Calif, Cooper Medical College, San Francisco, 1889, aged 74, died Oct 2, 1938, in the Sutter Hospital of lobar pneumonia and fractures of the leg and hip received in an automobile accident

**John William Chappell**, Washington, D C, Columbian University Medical Department, Washington, D C, 1881, member of the Medical Society of the District of Columbia, aged 82, died, Nov 2, 1938, of chronic myocarditis

**Clarence Parnell Holden**, Melrose, Mass, New York Homeopathic Medical College, New York, 1880, for many years chairman of the board of health, aged 85, died, Oct 8, 1938 of cerebral thrombosis and arteriosclerosis

**Holland Harvey Green** • Hillsboro, Va, George Washington University School of Medicine, Washington, D C, 1931, president of the Loudoun County Medical Society, aged 38, died, Oct 18, 1938, of coronary thrombosis

**Clark William Greene**, Binghamton N Y, Bellevue Hospital Medical College, New York, 1873, member and past president of the Medical Society of the State of New York, aged 89, died, Oct 1, 1938, of myocarditis

**Theodore Charles Guenther** • Brooklyn, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896, for many years on the staff of the Norwegian Hospital, aged 63, died, Oct 29, 1938, of embolism

**Frank Watlington Lester**, Pasadena, Calif, College of Physicians and Surgeons Medical Department of Columbia College New York 1878, aged 83, died, Oct 21, 1938 of cystitis and arteriosclerotic heart disease

**Albert S Kaufman** • New Kensington, Pa, Baltimore Medical College, 1893, formerly member of the school board on the staff of the Citizens General Hospital, aged 69, died, Oct 8, 1938 of arteriosclerosis

**Ferdinand P Henn**, Glendale, N Y, Long Island College Hospital Brooklyn, 1908, aged 55, died Oct 1, 1938, in St John's Hospital, Long Island City, of nephroma of the right kidney and bronchopneumonia

**Guy Edward Armstrong**, Pound Wis, Northwestern University Medical School, Chicago, 1909, served during the World War, aged 66, died Oct 14, 1938, in Marinette, of toxic myocarditis following diphtheria

**Jacob Weaver Royer**, Terre Hill, Pa, Jefferson Medical College of Philadelphia 1892, served during the World War, aged 71, died in October 1938 of benign hyperplasia of the prostate

**Samuel M Miller**, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1877, aged 84, died, Oct 6, 1938 of carcinoma of the face and arteriosclerotic heart disease

**Robert Hill**, Ipswich, S D, College of Physicians and Surgeons, Keokuk, Iowa, 1894, member of the South Dakota State Medical Association, aged 73, died, Oct 23, 1938, of uremia

**Susan Edgar Abbott Wooldridge**, Pittsburgh, Boston University School of Medicine, 1902, member of the board of education, aged 59, died Oct 10 1938 of rheumatic heart disease

**Elmer Willard Coe** • Youngstown, Ohio, Ohio Medical University Columbus 1896, on the staff of St Elizabeth's Hospital, aged 68, died, Nov 16, 1938, of cerebral hemorrhage

**Thomas C Allen**, Bernie, Mo, Barnes Medical College, St Louis, 1901, member of the Missouri State Medical Association, aged 65, died, Nov 18 1938, of cardiac hypertrophy

**Elmer Ellsworth Jackson**, Washington, D C, Howard University College of Medicine Washington, 1889, aged 77, died Oct 9, 1938, at Chillum, Md, of intestinal obstruction

**John H O Quinn**, Patterson Ga, University of Georgia Medical Department, Augusta 1898, aged 69, died Oct 30, 1938, of hemiplegia, myocarditis and hypostatic pneumonia

**Lewis Harmon Young**, San Francisco, College of Physicians and Surgeons, San Francisco, 1903, aged 69, died, Oct 13, 1938, of injuries received in an automobile accident

**Richard Craig Price** \* Denver, University of Colorado School of Medicine, Denver, 1919, aged 44, died Oct 29, 1938, of sclerosis of the coronary arteries and myocarditis

**Max Sturnick**, Boston, Harvard University Medical School, Boston, 1904, member of the Massachusetts Medical Society, aged 61, died Oct 24, 1938, of coronary occlusion

**Gomer John**, Promise City, Iowa, Keokuk Medical College, College of Physicians and Surgeons 1900, aged 70, died, Oct 28, 1938, of septicemia and lobar pneumonia

**Minnie Iland**, Crane, Ore., University of Southern California College of Medicine, Los Angeles 1907, aged 64, died, Oct 14, 1938, in Seattle of cerebral hemorrhage

**Edwin A. Boone**, Loyal, Okla., Keokuk (Iowa) Medical College, 1897, aged 78, died, Oct 22, 1938 in St Mary's End Springs Hospital, End, of coronary thrombosis

**Frederick W. Ireland**, Norwalk, Conn. Jefferson Medical College of Philadelphia, 1903, aged 63 died Oct 29, 1938, in Pembroke Ont., Canada, of cerebral hemorrhage

**Francis Charles Ligouri**, New Rochelle N. Y. University of Vermont College of Medicine, Burlington, 1899, aged 64 died Oct 15 1938 of coronary thrombosis

**Wesley Asbury Giffin**, Deckerville Mich. Detroit College of Medicine, 1891, served during the World War, aged 71 died, Oct 31, 1938 of coronary thrombosis

**John Franklin Hunt**, Dickson, Tenn. University of Nashville (Tenn.) Medical Department, 1900 aged 65, was found dead Oct 18 1938 presumably of heart disease

**William B. McDaniel**, End Okla. Barnes Medical College St. Louis, 1901 aged 69 died Oct 30 1938, of cerebral hemorrhage hypertension and diabetes mellitus

**Albert S. Yenni** \* New Orleans Medical Department of Tulane University of Louisiana, New Orleans 1897, aged 63, died Oct 1 1938 of carcinoma of the larynx

**Thomas M. Edwards**, Frostproof Fla. University of the South Medical Department, Seawater Tenn. 1900 aged 64, died, Nov 3 1938 of cerebral hemorrhage

**Bailey Campbell**, Dayton, Ohio Medical College of Ohio Cincinnati 1896, aged 72 died in October 1938 of myocarditis diabetes mellitus and chronic prostatitis

**Inez Hyatt**, Conneaut Ohio Ohio State University College of Homeopathic Medicine Columbus, 1915 aged 67, died suddenly Oct 15, 1938, of heart block

**Frank Augustine Gardner**, Salem Mass. Boston University School of Medicine 1883, aged 77, died Oct 18, 1938, of coronary sclerosis and thrombosis

**Daniel Lewis Youngs**, Clarksville Iowa Drake University Medical Department Des Moines, 1895 aged 73, died, Oct 31 1938, of arteriosclerosis

**William John Joseph Manning**, Norristown Pa. Jefferson Medical College of Philadelphia 1895 aged 70, died, Oct 4, 1938, of chronic endocarditis

**Edward L. Jones**, Raymond Neb. Lincoln Medical College of Colnet University 1905, aged 74 died Oct 12, 1938, of heart disease and hypertension

**Malcolm Osgood Austin**, San Francisco Cooper Medical College, San Francisco, 1895 aged 75 died Oct 23 1938 of carcinoma of the prostate

**William F. Hotchkin**, Blue Island, Ill. Chicago Homoeopathic Medical College 1896 aged 76 died in October 1938 of chronic nephritis

**Reginald Francis Scott**, Toronto Ont. Canada, University of Toronto Faculty of Medicine 1926 aged 40, died, Oct 14, 1938

**Louis Otto Saur**, Fosters, Ohio (licensed in Ohio in 1898), formerly health officer of Norwood aged 62 died, Oct 31, 1938

**Harry Bay** \* Cole Camp Mo. Barnes Medical College St. Louis, 1904, aged 59 was killed by a train Oct 28 1938

**William Archibald Kerr**, Elora Ont. Canada, Trinity Medical College, Toronto, 1899, aged 66 died Oct 16 1938

**George Theodore Urquhart**, New York, University of Toronto Faculty of Medicine, 1920, aged 47, died Oct 1 1938

**Stephen Henry Murphy**, Kentron Ont. Canada Trinity Medical College, Toronto, 1894, aged 74, died Oct 28, 1938

**Edna Zinn Juchhoff** \* Chicago, Chicago Medical School, 1927, aged 57, died Oct 7, 1938, of myocarditis

## Correspondence

### PNEUMONIA IN PRIVATE PRACTICE

*To the Editor*—I read with much interest the article by Drs Russell L. Cecil and E. A. Lawrence, "Pneumonia in Private Practice," in THE JOURNAL November 19. However, I am not able to corroborate the conclusions of the authors.

I have been engaged in the general practice of medicine in rural West Virginia since 1912. In that time I have treated approximately 100 cases of lobar pneumonia, with one death. I have treated approximately 150 cases of other types of pneumonia, with five deaths. These are not selected cases but run of the mine cases of general practice in rural West Virginia for the period indicated and include all the cases I have been privileged to treat. I have not sent any pneumonia patients to any hospital. One was taken to a hospital contrary to my advice and died there.

About one half of these cases occurred in the five years that began with 1918. So far as I know, the experience of the other rural physicians whom I have known best has not been materially different from my own. I do not know that pneumonia in rural West Virginia is any more mild than pneumonia in the shadow of the big city clinics, but somehow the country doctors have been able to maintain a better batting average.

One difference in case management which I have noticed is that in rural practice in this section the treatment is more personal with more attention to detail, and less standardized than in the large clinics.

I have had serum in my icebox for the past several months but have never used it. I have never used an oxygen tent.

E. R. COOPER, M.D., Glenville, W. Va.

[NOTE.—This letter was referred to Dr. Cecil whose reply follows.—Ed.]

*To the Editor*—Unfortunately there are no studies in medical literature which throw any definite light on the subject of pneumonia in private practice, particularly pneumonia in rural private practice. I have heard a good many country doctors claim that their death rate in pneumonia was very low but when one begins to question them more carefully it is almost impossible to get any accurate figures as to types, character of pneumonia or age of patient.

As a matter of fact, there is much ground for the belief that pneumonia in the country is considerably milder than it is in the large cities, with a correspondingly lower death rate. No doubt this is due largely to the fact that the severe types (types I, II and III) are rarely encountered in the country districts. However, I would be willing to go still further and admit that a hundred type I cases in the country would show a lower fatality rate than a hundred type I cases in the city. However, right here in New York City, Park Avenue practitioners boast just as Dr. Cooper does that they do not lose many of their pneumonia patients.

It is assumed that the virulent forms of pneumonia are spread by contacts with carriers. Such contacts are lacking in the country and for that reason the virulent forms of pneumonia are not so common among country people as they are among city people.

The doctors in the Southern states claim that pneumonia is milder in the South than it is in the North. But this is not borne out by statistics prepared by the life insurance companies or by the U. S. Bureau of the Census. West Virginia has a higher death rate than New York State, 93 per hundred thousand versus 85 per hundred thousand.

There seems to be rather general agreement that the fatality rate for pneumonia in the home is less than that for cases treated in hospitals. For example, in the final report of the

Massachusetts Pneumonia Study by Heffron and Robinson (Final Report of the Massachusetts Pneumonia Study and Service, 1931-1935, *Commonwealth* 24 24 [Jan-Feb-March] 1937) their cases are summarized as follows

	Cases	Deaths	Fatality Rate Per Cent
Home cases	138	70	20.7
Hospital cases	167	85	23.2

These figures check pretty well with the figures of Dr Rogers, director of the New York State Bureau for Pneumonia Control (Rogers, E S, and Gooch, M E Type I Pneumococcus Pneumonia Observations from Study of Two Thousand Cases Treated with Specific Serum, *New York State J Med* 38 1369 [Nov] 1938) His figures were quoted in our article and were as follows

	Cases	Deaths	Fatality Rate Per Cent
Home cases	551	74	13.4
Hospital cases	1 475	273	18.5

The figures of Rogers are more significant than those of Heffron, as they were all type I cases and were all treated with serum

These statistics are no reflection on hospital therapy They simply mean that the doctor keeps his mildly affected patients at home and sends his sick ones to the hospital

A careful bacteriologic study of rural pneumonia would be an important contribution to medical literature, but a large number of cases would have to be studied and the typing done by a first-class bacteriologist I suspect that there is a good deal of inaccurate typing done in rural and small-town hospitals

I cannot agree with Dr Cooper that the character of the nursing or medical care is a factor in the difference between the fatality rate in country and city practice Certainly no pneumonia patients in the world could have better or more personal care than they receive at the Hospital of the Rockefeller Institute, yet the death rate in a large series of type III cases at that hospital is 40 per cent!

RUSSELL L CECIL, M D, New York

### VALUE OF RETICULOGEN

To the Editor—Recently there has come to my attention the following statement, which appeared on page 15 in a small book entitled "The Anemias" published by Eli Lilly Company in 1938 "Reticulogen contains 20 units of anti pernicious anemia principle per cc"

I have also recently seen such a statement in the literature contained in a package of Reticulogen I know of several instances of such a statement being made to physicians by men representing Eli Lilly Company In at least one of these instances the physician was led to believe that this represents U S P units

I have seen no reference to Reticulogen in publications of the potency of anti-pernicious anemia substances made by the U S P Anti-Anemia Advisory Board There has been a statement made by this subcommittee that no parenteral liver substance would be given a rating of more than 15 units per cubic centimeter of material, and furthermore that mixtures with other substances would not be accepted for inclusion in the Pharmacopoeia (The Standardization of Liver Preparations, editorial, *THE JOURNAL*, July 16, 1938 p 254)

As I am not aware of the use of units in describing liver extracts other than those proposed by the U S P Anti-Anemia Advisory Board and because the company does not refer to any other unit it seems to me that this is a deliberate mis-

representation designed to sell this material to those physicians not familiar with the facts stated I believe that if such is the case the U S P Committee and the Council on Pharmacy and Chemistry should make these facts and the standing of this particular preparation entirely clear to all readers of *THE JOURNAL* On the other hand if this material has been tested and such potency has been approved by the Anti-Anemia Advisory Board it would be a great service both to the physician and to the patient with pernicious anemia to have this evidence made available

WILLIAM P MURPHY, M D, Boston

### "REPORT ON THE USE OF ROENTGEN RAYS FOR CONTRACEPTION"

To the Editor—The report by the Councils' Committee on Contraceptives appearing on page 1767 of *THE JOURNAL* November 5 errs in taking up a matter which does not fall in its jurisdiction That portion of the work of Harris and of Mayer, Harris and Wimpfheimer on the use of the roentgen rays to induce therapeutic abortion is not a method of contraception In a later portion of the report the committee condemns the method because "it is decidedly dangerous and its use should be deprecated"

The mandate of this committee is described in an editorial comment on page 1170 of the same issue of *THE JOURNAL* In this it is stated that the House of Delegates 'delegated to the Council on Pharmacy and Chemistry and to the Council on Physical Therapy the problem of investigating materials, devices and methods recommended or employed for the prevention of conception with a view to determining their physiologic chemical and biologic properties and effects' The committee is charged simply with studies affecting problems of therapeutic contraception and problems of sterility as well

Contraception, according to the definition in Webster's Dictionary, is "prevention of conception or impregnation" The function of the committee as I must conclude from the authorization by the House of Delegates does not include the study of measures for the interruption of pregnancy when established

The authors whom they refer to have not, as I must point out, advocated radiotherapy for the induction of sterility In fact, they emphasize that patients, after the conclusion of the treatment, are given instruction in methods of contraception The authors likewise state that, in spite of this contraceptive advice and the procurement of adequate devices, 35 per cent of the patients treated by radiotherapy conceived subsequently

The committee has interlarded between the opening and the concluding paragraphs twenty-two lines pertaining to inquiries concerning the use of the roentgen rays for the purpose of inducing criminal abortion and illegal sterilization The paragraph which presents an abstract of the two papers referred to, namely that of William Harris (*Am J Roentgenol* 27 415 [March] 1932) and that of M D Mayer, William Harris and Seymour Wimpfheimer (*Am J Obst & Gynec* 32 945 [Dec] 1936), gives an unbiased resume of these papers Then, however, follows a paragraph discussing the illegal use of roentgen rays to interrupt pregnancy and produce sterility in women In the concluding paragraph this discussion is continued and, without further paragraphing the method employed by the authors quoted is condemned as "in spite of the results reported by the workers mentioned in the use of roentgen rays for therapeutic abortion it is the opinion of radiologists and other members of the medical profession that this method is decidedly dangerous and its use should be deprecated" Even the most careful reader might draw the inference, whether this is warranted or not, that the motives of the workers mentioned are suspected

The 200 patients reported on by Mayer, Harris and Wimpfheimer were treated in the gynecologic service of the Mount Sinai Hospital between 1927 and 1936 under my personal super-

vision The method was first resorted to after the tragic death on the operating table of a patient with severe cardionephritis during the emptying of the uterus had emphasized the danger of the interruption of pregnancy in poor surgical risks.

The therapeutic abortions were induced only after the head of the gynecologic department, the head of the radiotherapeutic department and the head of the department referring the patient had agreed on the necessity of the measure. The underlying cause warranting the induction was required to be permanent and absolute. The most frequent underlying condition was chronic cardiovascular disease (seventy-four cases). Next came pulmonary tuberculosis (twenty-seven cases). For further details of the other scattered cases, I refer to the articles themselves.

As to the results obtained abortion resulted spontaneously in 90 per cent. The method failed in 4 per cent. The morbidity was 3 per cent (fever in 1 per cent, sharp bleeding in 2 per cent). The mortality was 0. This record of 200 consecutive interruptions of pregnancy in patients suffering from serious general diseases requires no apology.

If the Council on Physical Therapy should see fit to judge and condemn the method in question it has a warrant to do so, but such a report should be given independent of any possible application of the method for illegal practices. This report should be based on the opinion of competent roentgenologists, who should judge the merits of the use of roentgen rays for the induction of therapeutic abortion in the special instances in which it was employed.

ROBERT T. FRANK, M.D., New York

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### REDUCING DIET WITH STEAK AND POTATOES

To the Editor—Recently a patient told me of a physician who was reducing patients' weights by putting them on a so-called steak and potato diet. They were to eat a pound of steak twice a day and an Idaho potato with each steak and a glass of milk every other day. They were to take their vitamins either orally or subcutaneously. I can see how this diet would not be hard to take if one likes steaks but my conception of the proper way to reduce would be a balanced diet with a reduction of caloric intake. Frankly it sounds to me nothing short of pure hogwash. What do you think of such a diet? M.D. Michigan

ANSWER—Reduction diets are essentially starvation diets. Obviously the greater the starvation the more rapid the loss of weight. How to starve without serious physiologic disturbance is the scientific question. A good reducing diet should provide every essential generously except calories. The protein content of the diet suggested far exceeds metabolic needs. On the other hand the diet is dangerously low in vitamins A, B<sub>1</sub> and C, provides insufficient bulk for the average normal person and would barely meet the minimum requirement of the adult for calcium. Vitamin deficiencies can, of course, be made up by the use of concentrated vitamin preparations. There is no apparent reason for administering these subcutaneously, however, since all available vitamin preparations are effective orally in the amounts needed as dietary supplements. The total caloric content of a steak and potato diet cannot be easily estimated because it will be greatly influenced by the amount of fat in the meat. It is to be assumed that the instructions cover cooked potatoes and cooked steak with all visible fat removed. On this assumption the diet may be estimated to contain roughly 75 Gm of carbohydrate, 250 Gm of protein and 40 Gm of fat, which is equivalent to 1,660 calories. That such a diet might lead to consumption of body fat for energy requirements is, of course, undeniable. That it is an effective, safe and sane method of weight reduction remains to be demonstrated. Steffanson found it impossible to eat lean meat exclusively over long periods. It was only with a good supply of fat that he could maintain

good digestion. However, increasing the fat rapidly increases the calories. According to the Rose Laboratory Manual for Dietetics (fourth edition, New York, Macmillan Company, 1937) two pounds of the edible portion of porterhouse steak of average fat content may be expected to supply approximately 200 Gm of protein, 185 Gm of fat and 2,460 calories, while the edible portion of beef sirloin steak will supply approximately 170 Gm of protein, 168 Gm of fat and 2,200 calories. The Council on Foods has outlined the principles which should govern the selection of foods for the reducing diet in its report on "Foods for Weight Reduction" (THE JOURNAL, Aug. 8, 1936, p. 431). This report should be consulted. Helpful tables of food composition and further suggestions for the selection of a low caloric diet may be found in the section of diet in the new (1938) edition of the A. M. A. Internist's Manual.

### SIBSON'S FASCIA AND SEBILEAU'S BANDS

To the Editor—What is the distinction between Sibson's fascia at the apex and the endothoracic fascia? The anatomies describe Sibson's fascia but none does not describe the endothoracic fascia. Can you give me the anatomy of Sebileau's bands? They are extensions of the endothoracic fascia. M.D. California

ANSWER—Sibson's fascia (Francis Sibson, London physician, died in 1876, published "Medical Anatomy" in sections from 1855 to 1869) is a continuation above the first rib of the endothoracic fascia. The latter is loose and indefinite between the parietal pleura and the ribs more clearly recognizable on the diaphragm, and best developed over the cupula pleurae. It is described in Morris's Anatomy (Jackson). Above the first rib where the apex of the lung and cupula pleurae are crossed by the subclavian arteries and veins and the lower cords of the brachial plexus, the fascia outside (above) the pleura is better developed. This is Sibson's fascia. It extends in general from the transverse process of the seventh cervical vertebra to the dome of the pleura and to the upper margin of the first rib.

It contains three definite thickenings (Sebileau's bands—Sebileau, Pierre, L'appareil suspenseur de la plevre, *Bull. Soc. anat. de Paris* 1891, p. 410). These three bands are: 1. Superficial, fibrous (or more often muscular), extending from the anterior tubercle of the sixth and seventh transverse processes to the dome of the pleura and to the first rib lateral to the subclavian artery. It lies between the subclavian artery and the eighth cervical nerve. 2. Deep, fibrous, extending from the first rib 2.5 cm from its vertebral end forward dividing in a < shape around the first thoracic nerve to be inserted into the upper surface of the pleural dome. 3. Medial, fibrous vertebralpleural from the front of the body of the seventh cervical and first thoracic vertebrae to be inserted into the superomedial part of the pleural dome. 1 corresponds to a muscle well developed in the higher apes and described by Testut (*Bull. Soc. d'anatomie de Paris* 1883). The scalenus minimus when present (about 30 per cent) joins 1 and 2. Zuckerkandl described this fascia in 1877 (*Ztschr. f. Anat. und Entwickl.*). See also Applied Anatomy of the Lungs and Pleural Membranes, by J. S. Dickey, 1911, p. 361, and Testut, *Traité d'anatomie humaine*, 1901, volume IV, where Sebileau's bands are pictured (p. 473, fig. 408).

### EFFECTS OF ORCHITIS FROM MUMPS

To the Editor—A man aged 20 had a bilateral orchitis from mumps and had a stormy time with fever for more than three weeks. The two sides were affected in succession. A relative is afraid that the boy may develop eunuchoid symptoms. Is there any basis for such fear? M.D. California

ANSWER—Testicular atrophy is an important and fairly common sequel of orchitis from mumps. Atrophy is not noticed at first because it progresses slowly and there are no active symptoms. The atrophy begins, perhaps, in about two months after involvement and may continue for as long as one year. The atrophy varies in degree, the organ may be decreased in size from one fourth to one half or it may be reduced to the size of a large bean, becoming hard and insensible to pressure. After the orchitis has subsided, a variable amount of testicular damage remains. The seminiferous tubules are chiefly affected, resulting in a loss of sperm formation. If both testes are involved, the patient becomes sterile. The secondary sex organs and male characteristics, however, remain normal, the patient does not suffer from loss of libido and can perform the sex act satisfactorily. Rarely, however, a condition develops which is characterized by hypogonadism and gynecomastia. This is unusual, since even after surgical castration in a male who has already attained sexual maturity there may be no loss of the masculine characteristics.

## FEVER TUBERCULOSIS OR NEURASTHENIA

*To the Editor*—A woman aged 23 married and divorced three years complains of nervousness poor appetite burning on urination burning in the rectum edema of the ankles loss of weight and tiredness especially in the afternoon. She has been occupied as a clerk for the last three years. She has a past history of scarlet fever erysipelas Bartholin gland infection pleurisy and neuritis. She apparently recovered from all these. The tonsils and adenoids were removed eighteen years ago. She has menstrual periods every six weeks with dysmenorrhea the periods lasting three or four days. Examination revealed a blood pressure of 90 systolic 70 diastolic weight 92 pounds (42 kg) hemoglobin 80 the temperature is elevated in the afternoon to 99.6 F but in the morning and late in the evening is normal. The heart lungs and abdomen are normal. The cervix appeared slightly inflamed. The uterus was in the normal position slightly enlarged. The urine is normal and the Kahn test is negative. Cervical smear showed a moderate number of pus cells. X-ray examination of chest and lungs as interpreted by a roentgenologist is as follows: There is a long perpendicular heart. Mild linear thready shadows are noted on both sides of chest with a few soft subtending shadows extending into both apexes and outward toward the lung periphery. No definite lesions of specific infection are apparent. There is a thickening of the hilus glands on the left side of the chest. However in these mild incipient and borderline cases it is well to treat them as incipient tuberculosis. The sputum test revealed no tubercle bacilli. I have kept the patient from work put her to rest in bed with a nourishing and nutritious diet and have given her elixir of iron quinine and strychnine and calcium and calcidein tablets. On such treatment she has improved considerably gaining 10 pounds (4.5 kg) in one month she has overcome her nervousness edema of the ankles has disappeared and the blood pressure has gone up to 116 systolic 80 diastolic but there is one symptom that completely puzzles me. She has a normal temperature at all times except when she uses the telephone and when she has visitors or when she carries on a lengthy conversation then her temperature rises to from 99.2 to 99.8 F also causing her to perspire excessively. When she has discontinued using the telephone or has dismissed visitors the temperature recedes to normal in about half an hour. I would appreciate your assistance in explaining why this patient requires the elevated temperature. Could it be due to an emotional disturbance or is it due to a low grade tuberculous infection?

ANGELO L. VINCENTI, M.D. Chicago

**ANSWER**—Most of the details in this case are suggestive of neurasthenia. A diagnosis of tuberculosis should not be made on the indecisive roentgenographic evidence described, and the word tuberculosis should not be mentioned to the patient. It is unusual for the roentgenographer to suggest therapy. Nevertheless since tuberculosis has been considered it would be wise to apply a skin test with purified protein derivative to determine the sedimentation time, and to examine the chest every three months or more until the disease is ruled out with certainty. The complaint of burning on urination should be investigated further to ascertain the presence or absence of cystitis or other infection.

The history of elevation of temperature to fever levels after emotional excitement is a characteristic of a certain form of neurasthenia and simply seems to indicate an unstable nervous control. The existence of hypotension, menstrual irregularity, subnormal weight and excessive perspiration all seem to be part of the syndrome described in *THE JOURNAL* Oct 3 1936, page 1089, by H. A. Reimann in an article entitled "The Problem of Long Continued, Low Grade Fever." Detailed methods for diagnosis, management and reference to other work are given in that article.

## DERMATITIS FROM PHENOL FORMALDEHYDE RESINS

*To the Editor*—At a local factory where I am doing some industrial work we are using a water soluble phenol and formaldehyde solution (this is essentially liquid bakelite). At the present time we have two men who are sensitive to this preparation and I would appreciate any information you might have. Is there a modern textbook on the subject of the toxicity of the various chemicals used in modern industry?

H. A. CAMPBELL, M.D. Newark, Ohio

**ANSWER**—Dermatitis is common among workers handling phenol formaldehyde resins and is usually due to hypersensitivity to formaldehyde. In a study made by the United States Public Health Service (Skin Hazards in American Industry, Part II, Public Health Bulletin 229, September 1936, pp. 1-12) it was found that 80 per cent of such workers were sensitive to formaldehyde and the remainder to phenol, cresol or hexamethylenetetramine, which is an ingredient in certain resins prepared for molding.

In order to determine to which of these substances the patient is sensitive, patch tests can be performed with (1) a 4 per cent solution of formaldehyde, (2) a 2 per cent aqueous solution of phenol and (3) dry powdered hexamethylenetetramine. The patches may remain on the normal skin for twenty-four hours without causing a reaction. A sensitive individual will react to the patch of a substance to which he is sensitive.

To protect the workers against the irritants in phenol formaldehyde resins, manufacturing processes should be totally enclosed

If this is not possible, hoods with suction exhausts should be placed over open processes so that dust and fumes are drawn away from the worker and out of the room. The workrooms should be ventilated by intake and exhaust fans to remove dust and fumes. The floors, walls, ceilings and machines should be washed down or vacuum cleaned at frequent intervals to keep them free from dust and irritating chemicals. Clean work clothes consisting of long sleeves, long-legged underclothes and long-sleeved coveralls fastened at the neck and wrists, and rubber gloves extending under the sleeves of the coveralls, should be provided. New workers who are hypersensitive to the resins but who have only mild eruptions should be given protective ointments in addition to the protective clothing and allowed to work for a period of three or four weeks in the hope that they will develop an immunity or become "hardened." If this does not occur, they should be removed from the job. If the patient's livelihood depends on his continuing at the job, an attempt should be made to desensitize him to the chemical to which he is sensitive. This should be done by beginning with minute doses administered subcutaneously and gradually increased. The results of each injection should be carefully watched so as to avoid severe constitutional reactions.

A book on the subject of toxicity of the various chemicals used in modern industry has been written by Alice Hamilton (*Industrial Toxicology*, New York: Harper & Brothers, 1934). Public Health Bulletin 215 and 229, "Skin Hazards in American Industry, Parts I and II," describe industrial processes and their skin hazards in nineteen industries. These bulletins may be obtained by writing to the Surgeon General, United States Public Health Service, Washington, D. C.

## CALCIFICATION OF ARTERIES

*To the Editor*—I am seeking information regarding the time of onset of calcification of the arteries. Which arteries calcify first as demonstrated at autopsy or by x-ray examination and at what age does this calcification appear? Is it the same in the two sexes? What is the order of calcification of the various arteries? Is there any set chronological order for calcification of the various arteries? The reason for these questions is this. In a few patients complaining of coldness color changes and even nocturnal and rest pain in the lower extremities I have found no vascular disturbance to account for these symptoms. However in each case a lateral x-ray view of the lumbosacral region has revealed calcification of the aorta. This has led me to believe that there is also calcification of the arteries supplying the lower portion of the spinal cord with a resulting ischemia explaining the symptoms. In these cases there was no other demonstrable evidence of calcification and the ages varied from 47 to 66 years the age group in which calcification is a normal observation.

ROY J. POPKIN, M.D. Los Angeles

**ANSWER**—Calcification of the media is most frequent and most severe in arteries of the lower extremities. Monckeberg in 1903 in the pathologic study of fifty-five cases of medial calcification found the femoral artery involved in fifty-one, the tibial in thirty-six, the radial in twenty-one and the femoral alone in fifteen. In 1924 Lange in a pathologic study of 3,000 cases in which the age varied from 30 to 80 years found medial calcification in the lower two thirds of the femoral in 97 per cent, posterior tibial in 87 per cent, anterior tibial in 83 per cent, upper third of the femoral in 57 per cent, radial in 18 per cent, ulnar in 14 per cent, popliteal in 9 per cent and brachial in 2 per cent.

There is no doubt that calcification is much less common in the arteries of the upper extremity than in those of the lower. Several writers comment on the infrequency of medial calcification of the arteries of the brain except in the internal carotids, in which it is commonly seen roentgenographically. Faber found that calcification of the splenic, renal and hepatic arteries usually stops at the hilus. The large and medium-sized arteries in the substance of the kidneys are rarely calcified.

Lundsgaard and Rud in the roentgenologic study of peripheral arteries in 345 persons from 20 to 40 years of age demonstrated calcification in 52 per cent of men and 9 per cent of women. Joslin found calcification in 50 per cent of 345 patients with diabetes. Morrison and Bogan in 1929 presented a careful roentgenologic study of calcification of the vessels of the legs of 234 patients who had diabetes. They showed a steady increase in the incidence of calcification from the third to the eighth decade of life. Lansbury and Brown found x-ray evidence of calcification of the arteries of the legs in 65 per cent of men and 28 per cent of women older than 50 years.

Medial calcification begins in childhood and increases in intensity with age. It is usually not prominent macroscopically until after middle life. There is nothing available in the literature to indicate any chronological order for calcification of various arteries nor any information which indicates which arteries calcify first. It is probable, however, that those of the lower extremities are first involved with medial calcification.

Certainly routine roentgenograms of the pelvis indicate that calcification of the lower aorta and iliac arteries is common. The correspondent would probably have difficulty in getting authorities on vascular diseases to agree with his conclusion that roentgenologic evidence of calcification of the aorta indicates calcification of the lower portion of the spinal cord with resulting ischemia, for calcification itself does not indicate that there has been any significant interference with the chief function of the arteries, namely the transportation of blood.

Lansbury and Brown have summarized the situation as follows: "The clinical value of calcification of the arteries of the leg has been a debatable question. The finding, on roentgenographic examination, of definite degree of calcification, frequently leads to erroneous conclusions. It is clear, from this study and from other studies, that calcification is a normal process in older subjects and is more frequent among males than among females. Its presence by itself, therefore, in the absence of occlusive thrombosis, is not clinically significant. There has been a tendency to think that diverse, indefinite symptoms referable to the legs have a vascular basis, if calcification is present in spite of the presence of open arteries. Occlusion of the arteries is the essential process that produces arterial insufficiency, symptoms of claudication, ulcers and gangrene. The presence of calcification does not give any significant information as to the presence or absence of an occlusive process. Degenerative pathologic changes in the coats of the arteries do not, as far as is known, cause symptoms."

The correspondent is referred to Lansbury, John, and Brown, George. Clinical Significance of Calcification of the Arteries of the Lower Extremities (*Proc Staff Meet, Mayo Clin* 9 48 [Jan 24] 1934) and to Cowdry, E V. Arteriosclerosis (New York, Macmillan Company, 1933).

#### VOICE CHANGES IN BOY

To the Editor—I have seen a boy aged 14 years normal at birth weighing 7½ pounds (3 400 Gm). When 6 years old he had measles, mumps and whooping cough. At the age of 7 he had a severe case of influenza with empyema which cleared up on aspiration and washing with antiseptic solution. His tonsils were removed the following summer and he spent the following winter in Florida and has not been ill since. He started having the usual changes of puberty about eighteen months ago. These are all normal except for the voice which still breaks. At times he seems unable to make a sound. He is normal in weight and height, the weight being evenly distributed. The sex organs are normal and the pubic hair is normal in distribution and amount. He has never been shy but is becoming so on account of his voice. The acne vulgaris which he has shows no change. No treatments were given for one year. Lately I have given him 1 000 rat units of antuitrin S weekly for eighteen weeks with no apparent change. Should I continue this treatment? If so, how long and with what dosage? Is there a better treatment?

M D, Ohio

ANSWER—Most boys have the voice changes described in the query and recover spontaneously after a brief period. The boy should be advised not to use his voice excessively or stram his vocal cords at home or at school or on the playground. He should be assured that the changes are normal and that no permanent ill effects will result.

The antuitrin-S will probably have little or no effect, nor would any other glandular product, in the amelioration of this pubescent process. An occasional dose of bromide given internally would calm his nervous irritability and might aid in stabilizing his voice production.

#### INDICATIONS FOR ADENOIDECTOMY

To the Editor—1 Does the knowledge that adenoids are diseased warrant routine removal at the time of tonsillectomy? 2 Is it known definitely that the adenoid can be a focus of infection? 3 What are the possibilities as an obstruction to respiration?

M D Indiana

ANSWER—1 Adenoidectomy is always performed at the time of the tonsillectomy. The majority of the laryngologists remove the tonsils first, after which the adenoid masses are removed. This is the routine in almost all cases. No surgical operation should be undertaken when an acute upper respiratory infection is present or when an acute inflammation or infection is found to exist in any viscous organ, or in the presence of fever.

2 The adenoid may have just as serious focal possibilities as the tonsils, teeth or sinuses. Bacterial multiplication readily takes place in the deep crypts, in which, after removal, pus is often noted. From this source infection may travel down the nasopharynx to the oropharynx and laryngopharynx and to the tracheobronchial tree. Cultures taken from the crypts of removed adenoid masses show growth in all instances.

3 In many infants, and less frequently in older children, the adenoid masses obstruct respiration. Not infrequently infants

are unable to nurse adequately, with resultant nutritional disturbances. A careful history and examination by the attending physician will reveal, in most instances, the cause of this condition, and when the adenoid masses are proved to obstruct respiration or feeding their removal is clearly indicated, regardless of the age. It is good practice, therefore, to remove the adenoid masses only when respiratory obstruction exists, to promote free air passage in the early years of infancy, later the faucial tonsils can be removed, lymphoid elements in the epipharynx again being cleaned out at the same time.

#### TOTAL PROTEIN OF SPINAL FLUID

To the Editor—In Queries and Minor Notes in THE JOURNAL Oct 1, 1938, page 1318 Dr Robert M Harbin Jr asked for the best technique in estimating the total protein of spinal fluid. I was surprised that the method advised by Dr Kingsbury and Dr Clark was not mentioned. It is my impression that it is the choice of many of the large laboratories and hospitals in the country. I believe it is used in a routine manner at the Mayo Clinic. I am mailing a photostatic copy of one of the pages described in Todd and Sanford's textbook. I believe that this matter ought to be discussed further in THE JOURNAL.

CHESTER W LONG MD, Milwaukee

ANSWER—The method described by Denis and Ayer (*Arch Int Med* 26 436 [Oct] 1920) for the estimation of protein in spinal fluid and suggested in THE JOURNAL (Oct 1, 1938, p 1318) as a simple but satisfactory method for this estimation was based on the paper by Folin and Denis on "The Quantitative Determination of Albumin in Urine" (*J Biol Chem* 18 273, 1914), as was the paper by Kingsbury, Clark, Williams and Post on "The Rapid Determination of Albumin in Urine" (*J Lab & Clin Med* 11 981 [July] 1926), to which the writer refers. The latter method as adapted by Todd and Sanford (*Clinical Diagnosis by Laboratory Methods*, Philadelphia, W B Saunders Company, p 544) for spinal fluid protein probably offers the advantage of rapidity in large laboratories where many determinations are done in a routine manner but the accuracy can scarcely be as great as with the Denis and Ayer technique, since a test tube comparator is employed instead of a colorimeter. Furthermore, a special outfit comprising a specially lighted test tube rack containing standards would be required for the determination, whereas the Denis and Ayer method requires only regular laboratory equipment. More recently Ayer, Dailey and Fremont-Smith (*Arch Neurol & Psychiat* 26 1038 [Nov] 1931) have slightly modified the Denis and Ayer method.

#### HABITUAL DEATH OF FETUS

To the Editor—I have attended three women apparently in perfect health with negative blood Wassermann reactions and perfect kidney function. Each of them has had two consecutive stillborn infants just before term or during normal easy delivery. These were their only pregnancies. The babies were perfectly formed. In two cases death of the fetus had antedated labor by twenty-four hours or more so some maceration of the skin had occurred. One of these women was the second wife of a healthy appearing man whose first wife died subsequent to a toxemia from her dead fetus. What is the most likely cause of these events? Veterinarians tell me that entirely aside from brucellosis frequently weak or stillborn offspring occur from the same sire. This community is definitely in the garter belt and minor degrees of myxedema may be present. Two of these women were given corpus luteum and compressed wheat germ tablets throughout their second pregnancies without the desired effects.

EDWIN P RUSSELL MD Rome N Y

ANSWER—Habitual death of the fetus after viability and before term is not so rare. In spite of all modern additions to our knowledge, not much progress has been made in solving this problem. One should eliminate first of all syphilis, diabetes, chronic nephritis, lead, alcohol, coffee, tobacco and other poisonings, and blood diseases in both husband and wife. Then one should investigate carefully the state of the cervix and uterus, particularly for residuums of previous infection and for deformity.

In the scientific approach to the knowledge of these cases, one must investigate all the medical conditions present in both husband and wife and then also study the local conditions in the wife. The husband too with a chronic prostatitis or a chronic pyelitis may be the source of infection in the uterus or adnexa and cause recurrent abortions.

Among animals it is well known that some males cannot convey sufficient life spirit to the ovum to carry it through to term. For example, a cow will abort or produce nonviable calves with one bull and healthy calves from another.

The subject is too vast for detailed consideration here and the inquirer is referred to the seventh edition of De Lee's Principles and Practice of Obstetrics (Philadelphia, W B Saunders Company), in which most of the knowledge extant today has been summarized.

## ABSORPTION FROM VAGINAL MUCOSA AND UTERUS

*To the Editor*—1 Is there any absorption from the vaginal mucosa? If there is how much absorption takes place? 2 Assuming that there is absorption from the vaginal mucosa would a foul smelling thick lochia after a normal delivery cause any rise in the temperature curve? 3 Assuming a positive answer to question 2 what rationale is there in the use of douches such as sodium bicarbonate?

F E GROSSMAN M D Connelsville, Pa

**ANSWER**—1 There is no absorption from the intact vaginal mucosa. There can be absorption from a damaged vaginal mucosa. It is not probable that absorption in such a manner occurs often enough to be of practical importance.

2 Absorption from the uterus of toxins elaborated by organisms commonly of low virulence is by far the most common cause of temperature rises during the puerperium.

3 Douches are of no value save as a cleansing agent, and the potentialities of danger from them far outweigh any good that they might do.

## PITUITARY EXTRACT AND LABOR

*To the Editor*—Is there any harm in giving from 0.5 to 1 cc of solution of posterior pituitary after the birth of a baby and before the placenta is delivered?

M D Ohio

**ANSWER**—It is usually inadvisable to administer an oxytocic drug prior to the delivery of the placenta unless one is prepared to meet an occasional complication that is likely to arise. If solution of posterior pituitary is given before the completion of the third stage, it may interfere with the normal mechanism of placental separation. The partially or even the completely separated placenta may become incarcerated above a contraction zone which may develop between the lower segment and the corpus. This contraction ring may remain for several hours, defeating attempts at the expulsion of the placenta by Crede's procedure. In the event that there is no excessive bleeding, one can wait until this contraction zone relaxes sufficiently to allow the passage of the placenta. In the event that excessive bleeding does occur, it may be necessary to give the patient anesthesia to a surgical degree before it is possible to invade the uterus manually and remove the placenta. Although this complication is not frequent, its occurrence may be an additional hazard to the patient.

If solution of posterior pituitary is given just as the baby is being delivered, it will facilitate the separation of the placenta in most instances, thereby shortening the third stage of labor and perhaps decreasing the amount of hemorrhage. In many hospitals the administration of an oxytocic drug in this manner is almost a routine practice but it should not be resorted to in the home.

CAUTERIZATION OF CERVIX WITH RETRO  
DISPLACEMENT

*To the Editor*—Is cauterization of an eroded cervix contraindicated when there is a first or second degree retroflexion of the uterus?

M D Illinois

**ANSWER**—Cauterization of the eroded or ulcerated exposed vaginal portion of the cervix is not hazardous in patients with a retrodisplacement. Endocervical cauterization should be avoided because the necrotic debris tends to drain in a retrograde direction into the uterus and through the tubes.

## RENAL THRESHOLD FOR SUGAR AND AGE

*To the Editor*—In the average uncomplicated case of diabetes mellitus is there any notable change in the renal threshold for sugar as the patient grows older?

M D Ohio

**ANSWER**—No notable change in the renal threshold for sugar occurs in the uncomplicated case of diabetes mellitus as the patient grows older. Studies of the renal threshold in diabetic patients have yielded conflicting reports. Apparently it is true that the renal threshold is somewhat higher in diabetic patients than in normal patients, but it varies with individuals. It is well known, however, that the renal threshold may be materially raised in any diabetic patient who is undergoing severe infection or in whom arteriosclerotic changes are occurring.

## AMNIOTIC FLUID FOR ADHESIONS

*To the Editor*—What is the present status of opinion on the value of amniotic fluid for the prevention of postoperative abdominal adhesions?

M D New York

**ANSWER**—From both the experimental and the clinical standpoint, amniotic fluid appears to have definite value as a stimulant of the peritoneal defense mechanism and as a deterrent to the formation of abdominal adhesions. It also seems to have some value as a protection against postoperative peritonitis. Amniotic fluid has not been generally accepted, but it would seem that in case of widespread adhesions its use is indicated.

## Medical Examinations and Licensure

## COMING EXAMINATIONS

## STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in *The Journal* January 7 page 78.

## NATIONAL BOARD OF MEDICAL EXAMINERS

**NATIONAL BOARD OF MEDICAL EXAMINERS** Parts I and II. Medical centers having five or more candidates desiring to take the examination Feb 13 15 May 12 (Part II only—limited to a few centers) June 19 21 and Sept 11 13. Ex Sec Mr Everett S Elwood 225 S 15th Street Philadelphia.

## SPECIAL BOARDS

**AMERICAN BOARD OF ANESTHESIOLOGY** An Affiliate of the American Board of Surgery. Written examination Part I will be held in various cities of the United States and Canada April 8. Oral examinations for all candidates St Louis May 13 14. Applications must be filed not later than sixty days prior to the date of the examinations. Sec Dr Paul M Wood 745 Fifth Ave New York.

**AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY** St Louis May. If there are sufficient applications before Feb 15 to warrant holding an examination Philadelphia, November. Sec Dr C Guy Lane 416 Marlboro St Boston.

**AMERICAN BOARD OF INTERNAL MEDICINE** Written examinations will be held in various parts of the United States Feb 20. Sec Dr William S Middleton 1301 University Ave Madison Wis.

**AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY** General oral clinical and pathological examinations for all candidates Part II examinations (Groups A and B) will be held in St Louis May 15 16. Application for admission to Group A examinations must be on file in the Secretary's office by March 15. Sec Dr Paul Titus 1015 Highland Bldg Pittsburgh (6).

**AMERICAN BOARD OF OPHTHALMOLOGY** Written Various cities throughout the country March 15 and Aug 5. Oral St Louis May 15 and Chicago Oct 6. Sec Dr John Green 6830 Waterman Ave St Louis.

**AMERICAN BOARD OF OTOLARYNGOLOGY** St Louis May 12 13 and Chicago Oct 6 7. Sec Dr W P Wherry 1500 Medical Arts Bldg Omaha.

**AMERICAN BOARD OF PATHOLOGY** Richmond Va April 8 9. Sec Dr F W Hartman Henry Ford Hospital Detroit.

**AMERICAN BOARD OF PEDIATRICS** St Louis May 16. Appointments must be made before Jan 16 Cincinnati Nov 14 15. Appointments must be made before July 14. Sec Dr C A Aldrich 723 Elm St Winnetka Ill.

**AMERICAN BOARD OF RADIOLOGY** St Louis May 11 14. Sec Dr Byrl R Kirklin 102 110 Second Ave SW Rochester Minn.

## New York June Examination

Mr Herbert J Hamilton, chief, Bureau of Professional Examinations, reports the written examination held by the New York State Board of Medical Examiners in Albany, Buffalo, New York and Syracuse, June 27-30, 1938. The examination covered nine subjects. An average of 75 per cent was required to pass. Eight hundred candidates were examined, 604 of whom passed and 196 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
George Washington University School of Medicine (1936 3) (1937) (1938 6)	(1935)	(1935)	11
Georgetown University School of Medicine (1937)	(1938 7)	(1938 7)	8

## Book Notices

**The Pathology of Diabetes Mellitus** By Shields Warren M D Pathologist to the New England Deaconess Hospital Boston With a Foreword by Elliott P Joslin M D Second edition Cloth Price \$4.75 Pp 246 with 89 Illustrations Philadelphia Lea & Febiger 1938

This edition, appearing eight years after the first, is based on a larger experience in the subject than any one person has ever before accumulated. The total number of diabetic necropsies is 484. Nine were on children under 11 years of age, twenty-nine were on older children and adolescents, and eight were in cases of hemochromatosis. In addition, because, as Dr Joslin says in the foreword, the present case of diabetes is half surgical, Dr Warren has had the opportunity to study nearly as many biopsies as necropsies. "I am thankful," Dr Joslin adds, "for the training which Dr Warren received as editor of the volume of Preventive Medicine issued by the Harvard Medical School, because automatically a note of prevention of diabetes and its complications permeates the text." The motto on the wall of Dr Warren's "modern operating room" betokens this—*Mortui vivos docent*.

The years that have passed since the first edition of this book have brought new problems to the attention of pathologists. Are infants of diabetic mothers abnormally large with hyperplastic islands of Langerhans? What is the nature of the hepatomegaly in diabetic children? Why does arteriosclerosis in the diabetic patient tend to affect selectively the intrinsic arteries of the heart and the arteries of the leg? What part, in clinical diabetes, is played by the pituitary body? These and many other pressing questions receive consideration. Experimental diabetes, produced in dogs by Young in 1936 by injecting extracts of the anterior lobe of the pituitary body, has been confirmed by Best. Sections of the pancreas of such animals, given to Dr Warren by Dr Best, showed marked hydropic degeneration of the island cells. However, examination of the pituitary body by serial section in eighteen cases of diabetes,

and random sections of the pituitary body in twenty-six more cases, revealed no constant significant abnormality. Vacuolization of the basophilic cells of the anterior lobe, comparable to that described by Kraus, also was seen in control cases. The acidophils were normal in number except in one instance, adenomatous groups of cells, such as Kraus has stained, were not found.

The increase in size and weight of the liver in diabetes may be due to a variety of conditions and is not always associated with increased accumulation of fat. The content of fluid is important, study of some of the larger livers suggests hydrops of the cells rather than an excess of fat or glycogen. The abdominal pain not infrequently associated with hepatic enlargement in diabetes may result from stretching of the capsule, as suggested by Marble. This would imply rapid change of size, perhaps too rapid for deposition of fat, but quite compatible with fluctuation of intracellular fluid. However, in the nondiabetic cases of a series of diabetic and nondiabetic livers the total fatty acid was found to range from 22 to 43 per cent of the wet weight of fresh liver, whereas in the diabetic cases the range was from 41 to 108 per cent.

This book is a compact mass of such material of interest. The illustrations are excellent and the writing is concise and clear. It is highly to be recommended for all students of diabetes and pathology.

**A Report on the Provision and Distribution of Infective Material for the Practice of Malaria Therapy in England and Wales.** By Lieut. Colonel J. A. Sinton V.C. O.B.E. M.D. Ministry of Health Reports on Public Health and Medical Subjects No. 84. Paper. Price 6d. Pp. 22 with 2 illustrations. London: His Majesty's Stationery Office, 1938.

The author states that there may be serious objections to the method of inducing malarial attacks by direct blood inoculation from patient to patient, especially if the donor is suffering from dementia paralytica. Under these conditions the risk of transmitting a syphilitic virus, possibly one with neurotropic characters, to a noninfected patient should never be taken. For this reason, as well as for the reason that malarial strains transmitted from patient to patient sometime become less virulent and are frequently lost, the British Ministry of Health has established an official malaria laboratory at Horton. The monograph describes the way in which mosquitoes are raised, the method of inoculating them from infected patients, the conservation of infected mosquitoes, and the feeding of the infected animals until they are shipped to the various parts of England.

The table dealing with the results of the treatment of dementia paralytica by induced malaria is especially interesting. Statistics are given from the year 1927 to the year 1936 inclusive. About 700 patients were inoculated each year. These patients had all been institutionalized. Approximately 15 per cent were discharged from the various mental institutions as cured and a further 8 per cent were discharged as improved, making a total of approximately 23 per cent who had been benefited by the treatment. The death rate varies between a high of from 10 to 14 per cent in the case of some workers to a low of from 3 to 4 per cent in the case of others. The author states that this apparent contradiction of the rates of mortality is due to the timely administration of appropriate treatment and by careful nursing to keep the temperature within bounds and hold the infection in check and damp down its severity. This seems rather contradictory, since it is now believed by many investigators that the height of the fever is one of the important factors if not the most important factor in treating dementia paralytica.

The therapeutic possibility of *Plasmodium vivax*, *P. falciparum*, *P. malariae*, *P. ovale* and *P. knowlesi* have been investigated and the author states that *P. vivax* is the most useful plasmodium for routine distribution and the inoculation of the nonimmune type of individual, who forms the vast majority of the patients to be treated in the British Isles. It is further stated that the inoculation with *P. falciparum* may be dangerous and may quickly lead to fatal results. Infections with other species of *Plasmodium* have, however, been found useful in special circumstances. They are suitable for certain patients who have resisted infection with *P. vivax* or have developed but a mild infection after inoculation with this parasite, and also for patients who have previously had malaria and who have developed as a result some degree of tolerance to infection with *P. vivax*. *P. malariae* has proved especially useful under such

conditions. Several different strains of *P. vivax* derived from countries as far apart as India, Rumania and Madagascar have been tried at Horton in the practice of malaria therapy. The one selected as the most satisfactory from all points of view is the so-called Madagascar strain at present in use. The method of collecting infected blood and the preparation of blood for distribution is described. All in all, the monograph is a concrete presentation of the subject matter and is useful to the laboratory worker and physician who wishes to obtain specific knowledge in this field.

**Meningiomas: Their Classification, Regional Behaviour, Life History and Surgical End Results.** By Harvey Cushing M.D. Moseley Professor of Surgery, Harvard University, Cambridge, Massachusetts. With the collaboration of Louise Eisenhardt M.D. Assistant Professor of Pathology, Yale University School of Medicine, New Haven, Connecticut. Cloth. Price \$15. Pp. 785 with 686 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1938.

This beautiful monograph is a masterly description of the experience of the senior author with the tumors of the meninges. After an account of their pathology and an enumeration of the cases, various types are discussed in particular situations in the cranial and spinal cavities with illustrative histories. The latter are often interesting and dramatic. It is difficult to imagine a more thrilling story than that of the two cases in chapter XXVI. The experiences recounted will long be an inspiration to every surgeon who attempts to remove these tumors. The book is beautifully printed in a clear new type which makes it easy to read. It concludes with a record of the operative mortality, which has been reduced to 8.9 per cent. This astonishing result is the crowning achievement of the life of a great surgeon, who has done more than any other to establish neurosurgery on a sound basis. If the art falls into disrepute because of present practices it will be from neglect of the main lesson which he attempted to teach.

**Pseudo Tuberculosis in Man. Part I. Besnier-Boeck's Disease. Visceral Localisation of the Sarcoids of Boeck.** By Prof. I. Snapper and Dr. A. W. M. Pompen. Part II. Regional Iletitis. By Prof. I. Snapper. Lectures Given in November 1937 at the University of London. Cloth. Price 7.50 florins. Pp. 90 with illustrations. Haarlem: de Erven F. Bohn, N. V., 1938.

This carefully prepared booklet is edited exceptionally well and includes twelve high grade halftone plates. Each plate contains from four to six individual black and white illustrations of roentgenograms, photographs, photomicrographs or drawings. This English edition is well written and will remain a classic for some time. Twenty-seven pages of appendices present thirteen detailed reports of Besnier-Boeck's disease and six case reports of ileitis regionalis. The first part of the volume is confined to a consideration of a new chapter in internal medicine, i.e. the story of the visceral localization of the so-called lupus pernio (Bernier, 1889) and the multiple sarcoids of the skin (Boeck, 1899). These disorders, which were considered by most clinicians as cutaneous tuberculids, are not confined to the skin alone and have become of great interest to general medicine, augmented by increased doubt concerning the supposed tuberculous etiology of this group of diseases. Boeck originally chose the name "sarcoids of the skin" because he first thought them related to the ill defined pseudoleukemias, but in 1900 he concluded that they were purely inflammatory lesions and changed the name to "benign miliary lupoid" with a certain similarity to lupus vulgaris. However, the title "benign sarcoids" persisted. Although opinion prevailed that this represented solely a disease of the skin, Boeck was of another belief. In 1905 he opined that the sarcoids were caused by a benign or uncommon form of the tubercle bacillus. In 1914 Schaumann demonstrated that the sarcoids of Boeck and lupus pernio were histologically the same disease and elaborated the conclusions of Boeck as to the constitutional character of the sarcoid lesion and its tuberculous etiology. The authors' attention to this remarkable syndrome began in 1935 when a patient whose illness during life presented great diagnostic difficulties showed the presence of Besnier-Boeck's disease at necropsy. This led to a review of cases seen previously, and finally observations were made in thirteen cases which demonstrated that this diagnosis must always be considered in cases of enlargement of hilar glands without obvious tuberculous etiology. Eight cases showed pulmonary localization, skeletal changes were present in five, eye

symptoms in five, spleen in seven, skin in seven and liver in four. Examination of the blood showed no typical abnormalities. The Pirquet test was negative nine times and positive twice. The prognosis on the whole is favorable. In none of the authors' cases did symptoms of active tuberculosis develop. The authors believe that the histologic structure of the nodules lacks the characteristics for a diagnosis of tuberculosis. In opposition to Schaumann, patients with Besnier-Boeck's disease do not often die of tuberculosis. This classic seems destined to stand as a lasting monograph on a disease which will frequently tax clinical diagnostic ingenuity, and it is well worth reading for its practical historical value concerning a disease which must be studied in man alone for the present. As long as the etiology remains obscure it seems historically justifiable to describe this syndrome as "Besnier-Boeck's disease." No specific therapy is known.

In the second part of the monograph, another pseudo-tuberculous disorder is noted which has been recognized during the last few years and has no tuberculous etiology, the so called isolated hypertrophic ileocecal tuberculosis. The six cases described typify the diagnostic difficulties that regional ileitis may present. A long period of unexplained intestinal symptoms leads to swelling in the lower right quadrant of the abdomen, and incomplete stenosis of the ileum develops. Nothing but methodical examination will establish the existence of regional ileitis. Many cases have a completely atypical symptom complex. Resection of the diseased ileum and adjacent part of the cecum may be necessary. The monograph includes twenty-nine references to Besnier-Boeck's disease and ten to ileitis regionalis.

**Diseases of the Nose Throat and Ear. Medical and Surgical.** By William Lincoln Ballenger MD FACS and Howard Charles Ballenger MD FACS. Assistant Professor of Otolaryngology Northwestern University School of Medicine Chicago. Seventh edition. Cloth. Price \$11. Pp 1030 with 576 illustrations and 30 plates. Philadelphia Lea & Febiger 1938.

The appearance of a textbook in a seventh edition is presumptive evidence of its popularity. The work of the two Ballengers (the older of the two unfortunately dead for some years) has for a long time held a prominent place among standard works on otolaryngology. Although the present edition has about a hundred less pages than the previous one it is even more complete. By careful revision, obsolete and repetitious material has been eliminated. There has been some rearrangement in the presentation of subjects as compared with the sixth edition. In the present volume part one covers the nose and accessory sinuses instead of the ear. It includes chapters on clinical anatomy and physiology of the nose and accessory sinuses, surgical correction of facial deformities, epistaxis, rhinoscleroma, allergy, nasal neuroses, the etiology, pathology, symptoms and diagnosis of sinus infections and the surgical treatment of sinus infections. Part two is devoted to the pharynx and fauces and includes such subjects as surgical anatomy, diseases of the tonsils, tonsillectomy, deep neck infections and functional neuroses of the pharynx. Part three discusses the diseases of the larynx, including the anatomy, malformations, diverticula, diphtheria, laryngeal paralyses and neuroses, as benign and malignant neoplasms of the larynx, tracheotomy and defects of speech. Part four deals with the ear in an extensive manner. Among the chapters are those on clinical anatomy and physiology, the functional tests of hearing, aural malformations and neoplasms, acute and chronic otitis media, petrositis, facial paralysis, brain abscess, otosclerosis, physiology, functional testing and surgery of the labyrinth. Part five presents bronchoscopy, direct laryngoscopy, esophagoscopy and gastroscopy. There has been fine cooperation in the preparation of this book on the part of Gabriel Tucker and Chevalier L. Jackson in the revision of the chapters on peroral endoscopy, the work of Dr Jackson in rewriting the chapter on gastroscopy, the thorough revision by Alfred Lewy of his section on physiology and functional testing of the labyrinth, and the description by J. M. West of his intranasal operation for dacryostenosis. The text is embellished with numerous illustrations. There are many bibliographic references and a complete authors' and general index. The various subjects are clearly and logically presented, the headings are strikingly designated in large type, and the vast amount of data stated concisely but without omission of any

essential facts. Indeed, this volume covers the whole field of otolaryngology more completely, especially from the practical point of view, than some other more extensive publications. In a word this work is easy to read, authoritative, comprehensive and highly informative. It will serve to great advantage students, practitioners and teachers who concern themselves with diseases of the ear, nose, throat, bronchial tree and esophagus.

**Ergebnisse der biophysikalischen Forschung in Einzeldarstellungen.** Herausgegeben von Professor Dr. B. Rajewsky, Direktor des Kaiser Wilhelm Instituts für Biophysik in Frankfurt am Main. Band I. Ultrakurzwellen in ihren medizinisch biologischen Anwendungen. Von H. Dünzer, H. E. Hollmann, B. Rajewsky, H. Schaefer und E. Schliephake. Paper. Price 19 marks. Pp 308 with 188 illustrations. Leipzig, Georg Thieme 1938.

This volume on ultrashort waves in their medical-biologic applications is the latest contribution to that field by German physical therapy. This work is the first volume of a symposium called "The Observations of Biophysical Research" being assembled by Professor Rajewsky.

In no sense a handbook for everyday use by the physician, it is essentially a rigorously theoretical textbook for advanced study. The subject matter is in large measure intelligible only to a properly qualified physicist. This becomes evident from a cursory examination of chapter headings.

**Introduction.** Actual problems of biophysical research in the field of short and ultrashort waves.

**Chapter 1.** The physical and technical fundamentals of ultrashort wave therapy.

**Chapter 2.** Biophysical foundation of ultrashort wave action in living tissue.

**Chapter 3.** Theory of the reactions of biologic bodies in the high frequency fields.

**Chapter 4.** The problem of treating biologic bodies in an ultrashort wave radiation field.

**Chapter 5.** The present position of clinical experience in ultrashort wave therapy.

The various chapters are prepared individually by the authors in the indicated sequence, each author being considered an expert in his subject. The most interesting and most valuable portions of the book are the highly theoretical sections. These contain a wealth of experimentally obtained data, tabulations and graphs on the electrical properties of different tissues and a profusion of mathematical formulas and proofs not obtainable elsewhere in medical literature.

Much of the subject matter is recent. Magnetron and Barkhausen-Kurz circuits are discussed, centimeter and decimeter waves are investigated from every angle, polar substances and the theory of dipoles are fully explained, and a complete chapter is devoted to the radiation field as distinguished from the capacity and induction field.

In contradistinction to the thoroughness with which the higher branches are investigated, the elementary aspects of the subject are skimmed through or overlooked. The fundamental electrical considerations are inadequately treated, dosage is superficially discussed and dismissed, and the clinical studies are entirely unsatisfactory, being merely reshaped and condensed from Dr. Schliephake's book, which is familiar to many American readers.

Taking the good with the bad, however, this work is entitled to a place on the reference shelf of every well equipped biophysical library and laboratory.

**A Study of Epidemic Influenza With Special Reference to the 1936-7 Epidemic.** By C. H. Stuart Harris, C. H. Andrews and Wilson Smith with D. K. M. Chalmers, E. G. H. Cowen and D. L. Hughes. Medical Research Council Special Report Series No. 228. Paper. Price 80 cents. 2s. 6d. Pp 151 with illustrations. New York: British Library of Information. London: His Majesty's Stationery Office. 1938.

The authors have made careful studies of four small outbreaks of respiratory infections in which no virus was isolated and one widespread epidemic of influenza in which several strains of influenza virus were obtained. They correlated clinical symptoms in the various outbreaks but were unable to show a characteristic group of symptoms that would distinguish "epidemic influenza" from febrile catarrh. The latter third of the report discusses laboratory studies with the influenza virus. The section on isolation of the virus can be followed by those who wish to make experimental studies with the influenza virus. The

section on antibodies in human serum is of academic interest. Efforts to immunize human volunteers with vaccine made from a highly virulent strain of virus were attempted. The authors concluded that "proof of the efficacy or uselessness of vaccination must await further trials in future epidemics."

**Practical Microbiology and Public Health for Students of Medicine Public Health and General Bacteriology** By William Bernard Sharp M.D. Ph.D. Professor of Bacteriology and Preventive Medicine in the Medical Department of the University of Texas Galveston. Cloth Price \$4.50. Pp. 492 with 125 illustrations. St. Louis: C.V. Mosby Company, 1938.

This book is essentially a laboratory manual in bacteriology, immunology and public health. With directions for procedure it also includes a number of examples of charts of various kinds for recording the growth and other characteristics of bacteria. While not a manual worth reading by itself (nor is it intended to be), its real value can be demonstrated only when used as a guide in actual laboratory work.

**Base para interpretación de la radiografía de tórax del adulto. La imagen en el sujeto sano (proyección dorso ventral)** Por I. J. Pardo. Paper. Pp. 115 with 67 illustrations. Caracas: Lit. y tip. del Comercio, 1937.

Realizing that the interpreter of pulmonary roentgenograms must not place undue emphasis on appearances which are of almost universal occurrence, the author of this little book has initiated a series of studies to throw more light on the interpretation of the roentgenogram of the adult chest. In Venezuela the author has evidently taken a lead in seeking to perfect our knowledge of this subject. This little volume deals with the postero anterior projection of the healthy subject. It is assumed and hoped that further, equally meritorious, studies may follow in due time. The study was begun in Spain but the revolutionary events caused the author to continue his work in Caracas. Nearly all of the clinical material came from the dispensary of the Autonomous University of Barcelona. The discussion includes general questions relating to radiography, the extra-thoracic soft parts, the skeleton, the diaphragm, the accompanying shadows and other soft tissue intrathoracic elements, the mediastinal shadow, the lung, the pleura and the calcifications which represent the primary tuberculous lesions. The book justifies praiseworthy criticism.

**Handbook of Histological and Cytological Technique** By R. R. Bensley and S. H. Bensley. Department of Anatomy, The University of Chicago. Cloth. Price \$2. Pp. 167. Chicago: Illinois University of Chicago Press, 1938.

This little manual of histologic technic differs from most others available by the fact that it emphasizes some of the excellent methods and points of view of R. R. Bensley. It differs further from most others in not being overburdened with the rarely used and to a great extent unnecessary methods. Most of the methods which are detailed are clearly stated although some are unnecessarily complicated. The beginner will be lost in the extreme detail and lack of precise directions in the section dealing with sectioning and mounting. This is especially true of that part dealing with the microtome knife. The short discussion on glands is especially informative from the point of view of histochemistry. One of the best sections in the manual is the excellent presentation of the principles of staining. It contains a brief history of the use of stains and an instructive outline of the accumulated data on the underlying reactions which occur in various staining processes. Indeed, the chief value of the manual lies in the emphasis placed on these principles underlying staining technics.

**Health Hygiene and Hokey** By W. W. Bauer, M.D. Cloth. Price \$2.50. Pp. 322. Indianapolis & New York: Bobbs-Merrill Company, 1938.

This is more than another book for public consumption on debunking of health fads. In addition to this aspect it contains many common sense suggestions for normal living. The author writes entertainingly and simply in a strictly accurate manner. Several of the alliterative chapter headings illustrate the readability, such as "Soft Soap and Skin Games," "Dispelling Dietary Dilemmas," "Brains, Biceps and Bunk." As a guide for sensible living it can be safely recommended to patients especially those most inclined to follow the miscellaneous advice of friends and relatives.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Medical Practice Acts Unlicensed Cancer Specialist Enjoined**—The defendant, W. W. Cooper of Altoona, Kan., was, in a suit instituted by the state of Kansas, on the relation of the attorney general, enjoined from practicing medicine without a license. He appealed to the Supreme Court of Kansas.

According to the evidence, the defendant was 86 years of age and for many years sold what the court referred to as "Baker's medicines, household remedies." Eventually he prepared a cancer "remedy" of his own, in the form of a paste, which was applied to the affected part of the body. An investigator, apparently employed by the State Board of Registration and Examination, consulted the defendant concerning a mole under his arm, during September of 1936 and May of 1937. During the first consultation, the defendant advised the investigator that the mole was a cancer but that it could be cured for a fee of fifty dollars. The investigator paid three dollars at the time and the defendant put some paste on adhesive tape and applied it to the mole, telling the investigator to return in about two weeks. Immediately on leaving the defendant's residence, the investigator removed the paste. He returned again in May 1937 and a similar treatment was given. On leaving, the investigator again promptly removed the paste and it was delivered to a chemist for analysis. At the trial, the chemist testified that his analysis showed that the paste contained "about 50 per cent chloride of zinc, starch, and some vegetable tissue, indicating it was a mucilaginous drug called 'althaea'."

The defendant contended that he was not engaged in the practice of medicine or surgery. But, the court said, the answer to that contention is found in the medical practice act, which declares that any person shall be regarded as practicing medicine and surgery who shall prescribe or recommend for a fee, any drug or medicine for the cure or relief of any infirmity or disease of another person. It cannot be doubted, the court continued, that the practice in which the defendant engaged, without a license, was clearly prohibited. Furthermore, the evidence of the defendant was not that his compound constituted a domestic remedy, the administering of which was exempted from the medical practice act. His evidence was quite to the contrary. It was to the effect that the remedy could be applied by any one without danger who had access thereto. He contended, however, that it was a combination of drugs known only to himself. For this knowledge, claimed to be possessed solely by himself, and for the treatment of the patient, he charged a fee. The defendant further contended that the prohibition of the practice as conducted by him violated his inalienable rights, but he cited no authorities in support of this contention. The law does not prohibit the practice of medicine and surgery, the court observed. It simply prescribes certain requirements with which the defendant and others must comply in order to qualify for practice. Such legislation constitutes a valid exercise of police power.

Ordinarily, the court said, the commission of crime may not be enjoined. The legislature of Kansas, however, has by statute authorized the use of the injunctive process to enforce the provisions of the medical practice act. Such a statute is not invalid as authorizing an injunction against an act made criminal or as denying the right to a jury trial in criminal prosecutions. Punishment for violation of such injunction would be for contempt of the order of injunction and not punishment for violation of a criminal statute. These principles, the court said, have been clearly recognized in cases of injunction under medical practice acts and similar legislation.

The question at issue the court said, was not how much benefit or harm resulted from the defendant's treatments but whether he was authorized to do what he did and what he intended to continue to do, without a license. The defendant's own admissions, concluded the court, disclosed that his practice was not within the law. The judgment for the state was therefore affirmed.—*State ex rel Beck, Atty. Gen. v. Cooper (Kansas) 78 P. (2d) 884*

**Compensation of Physicians Liability of Motorist on Oral Promise to Pay for Medical Services Rendered Accident Victim**—The defendant's wife, while driving her husband's automobile, ran over a little girl and fractured her spine. The defendant personally made arrangements for the plaintiff, a bone specialist, to attend the girl, promising orally to pay the medical and hospital bills. After the child had recovered, the defendant refused to pay for the services rendered and the plaintiff sued. He recovered a judgment against the defendant, who thereupon appealed to the Supreme Court of Oklahoma.

The defendant contended that the promise he made to the plaintiff to pay the medical bills was not a valid, direct promise, based on a valuable consideration, but was an oral promise to answer for the debt of another, which was not binding on him. But, said the court, the evidence reasonably sustained the finding by the trial court that the promise was made directly to the plaintiff, with no conditions or contingencies attached to it whatever. The plaintiff so testified, and the reasonable probabilities, in view of all the circumstances, corroborated and gave credence to his testimony. In the opinion of the court, it was clear that the plaintiff's promise to perform the services, followed by the performance, was a sufficient consideration for the promise to pay. The fact that the child did not belong to the defendant was immaterial nor was the question whether the defendant was under any legal or moral obligation to the child or to its parents to furnish medical attention conclusive of the case. The important fact was that, regardless of the foregoing, the plaintiff did perform professional services in reliance on the defendant's promise to pay therefor.

The defendant's promise was not that he would pay if the father of the child did not pay. The promise was an original undertaking, it was not a promise to answer for the debt, default or miscarriage of another so as to bring it within the statute of frauds. The rendering of professional services, the court said, so far as the present question is concerned, is governed by the same rules as apply to the furnishing of goods. When a person orally promises to pay for goods furnished to another, if the oral contract creates original liability on the part of the promisor and credit is extended solely to him, it need not be in writing to be valid. If it is the intention of the promisor to pay only in case of default of that other party, such contract is within the statute of frauds and must be in writing to be valid. The court thought that the present case was similar to *Ward v. Archer*, 173 Okla. 465, 52 P. (2d) 758, in the third court syllabus of which it was said:

A person who promises to pay physician's and surgeon's fees and hospital expenses for one injured by a son of the promisor is bound thereby and when this state of facts is found by the court trying the case without a jury no other primary liability or promise appearing the promise is not within the statute of frauds.

The defendant finally contended that the trial court erred when it sustained an objection to his question put to the plaintiff on cross-examination, inquiring of the plaintiff whether, if the father of the child had offered to pay the bill, the plaintiff would have refused it on the ground that it was an obligation of the defendant's. The defendant stated that the purpose of the question was to ascertain whether the plaintiff regarded defendant's promise as original. No doubt, the court said, the plaintiff, acting as the ordinary prudent person who is willing enough to receive payment of that which is owed him, would have accepted it regardless of whom he considered liable. The court could not see that it made any material difference whether the question was permitted or excluded.

The judgment for the plaintiff was therefore affirmed—*Proctor v. Sisler* (Olla) 78 P. (2d) 802.

**Chiropody Employment by Corporation of Licensed Chiropodist Lawful**—The defendant corporation operates a shoe store in Manhattan, in which it sells accessories such as arch and ankle supports, pads and plasters. In fitting shoes its salesmen use a mechanical device known as a pedograph, which indicates the outer physical characteristics of the customer's foot and aids in determining the proper width, length and size of the shoe or of the arch support if one is required. The defendant employs a licensed chiropodist and a registered nurse,

who gives vibratory foot massage treatments under the supervision of the chiropodist. A salesman took a pedograph imprint of the feet of an investigator, posing as a customer. In response to questions, he described what he said were abnormal conditions in her feet and then recommended a course of treatment by the chiropodist employed by the defendant. Later the investigator and a companion received from the chiropodist and the nurse the treatments suggested by the salesman. The defendant was thereafter prosecuted for unlawfully practicing chiropody and was convicted. The appellate division of the supreme court affirmed the judgment, and the defendant appealed to the Court of Appeals of New York.

At common law, said the Court of Appeals, any person could lawfully treat deformities and functional disturbances of the feet. In 1905, however, the legislature enacted a law forbidding any person not theretofore legally authorized to practice chiropody in the state of New York to engage in such practice without a license. Neither that law nor any amendment to it restricts specifically the employment by corporations of licensed chiropodists. It was contended on behalf of the prosecution, however, that in providing that "no person" shall practice chiropody without a license the law barred the employment of a licensed chiropodist by a corporation, because a corporation is a "person" and cannot be licensed. But, said the court, the law does not mention corporations and on its face has no applicability to corporations. Its obvious purpose is to protect the public health by prohibiting any one from treating or diagnosing foot ailments unless qualified and by requiring such qualification to be shown by the possession of a license. In the field of pharmacy, the court pointed out, attempts to confine ownership of drugstores to licensed pharmacists, or to corporations whose stock is owned solely by licensed pharmacists, have been declared unconstitutional, on the ground that such a requirement has no relation to public health. The court did not think it material in determining the present question that corporations have been denied the right to practice law, medicine and dentistry. Between physician and patient, dentist and patient, and lawyer and client there is a confidential and trust relationship which does not exist between the chiropodist and those whom he treats.

The use of the pedograph as a mechanical aid in determining the proper size of the shoe required does not constitute, the court said, the practice of chiropody. With respect to the statements made by the salesman in answer to inquiries of the customer, it would be an unreasonable and harsh construction of the law, the court thought, to hold that it was intended to prohibit shoe salesmen from pointing out to customers the manifest abnormalities of their feet when questions are put to them by the customers. The salesman at no time held himself out as being a chiropodist or as being able to practice chiropody. On the contrary, he referred the customer to the licensed chiropodist. The nurse who gave massage and vibratory treatments under the direction of the licensed chiropodist was not practicing chiropody any more than a nurse who assists a physician is practicing medicine.

The judgment of conviction was therefore reversed—*People v. Dr. Scholl's Foot Comfort Shops, Inc.* (N. Y.), 13 N. E. (2d) 750.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Prevention and Correction of Facial Disfigurement**—Blair and his associates state that all fractures about the face should be reduced and the fragments held in their normal position before solidification commences. For those of the lower jaw and the tooth bearing area of the upper jaw the reduction should be as early as possible. Compound fractures of the lower jaw should be drained by external incision. With most injuries of the soft tissue it is better practice to let the wound heal spontaneously than to indulge in early debridement or to run the risk of suture scars. Tattooed wounds, whether from road oil or from gunpowder, should have the foreign matter removed early, the former by vigorous washing with a stiff brush after anesthetizing the surface, the latter by cutting out each individual grain with a needle pointed knife. In seeking gross foreign bodies in an open wound, the finger will sometimes detect what the roentgenogram and the eye miss.

**Injuries to the Hand**—Harmer believes that prompt attention to minor cuts of the hand may avert serious consequences and that what is done when the patient is first seen frequently determines the course and outcome. Errors of omission or commission at the first treatment of a relatively simple injury to the hand may lead to consequences so serious that the functional result, even after a long period of illness with one or more operations, may be pitiful. The author emphasizes the importance of (1) systematic preoperative examination based on anatomy and physiology, (2) appropriate instruments, (3) adequate exposure and gentle, deliberate technic to minimize operative trauma, (4) early active motion directed toward the restoration of function in cases of sutured or grafted tendons accompanied by guarded limitation of antagonistic muscles, and

(5) the importance of early active motion in cases of neuro-rhaphy accompanied by the employment of devices which permit the use of unaffected muscles but coincidentally prevent strain on the nerve suture and on the affected muscles during the reestablishment of their innervation.

- Acute Hematogenous Bursitis M B Cooperman Philadelphia—p 1094
- Chronicized Beef Tendon for Internal Fixation of Fractures F P Strickler Louisville Ky.—p 1102

**Toxic Myelopathy**—Kelman and Abbott suggest that, if spinal anesthesia were not given patients with severe myocardial damage, hypertension, marked hypotension and psychoneuroses as well as congenital anomalies, the number of complications following its use would be diminished. The spinal anesthetics commonly employed have been shown to be both myelolytic and hemolytic. When injected into dogs they produce an aseptic meningeal reaction with an exudation of plasma cells and a proliferation of arachnoidal cells, which later results in a thickening of the meninges, disintegration of axons and degeneration of the peripheral portion of the cord. Somewhat similar changes have been demonstrated in the spinal cords and nerve roots of patients dying after spinal anesthesia (procaine hydrochloride). As an anesthetic, spinal anesthesia has about the same immediate mortality and death rate from postoperative pneumonia as has ether but is superior to it in that it produces greater muscular relaxation and does not have the ill effects which follow ether. Almost any part of the central nervous system may be affected, with the involvement remaining permanent or causing a fatality, but if the foregoing contraindications are recognized the complications and mortality incident to spinal anesthesia should become negligible. Four cases of toxic myelopathy following spinal anesthesia are reported.

**Ligations on Nerves of Extremities**—Allen has shown in other studies that ligations of the limbs result in an instructive form of shock and also that the resistance to local asphyxia is greater than is commonly supposed, since the limbs of animals can survive complete lack of circulation for at least fifteen hours and the same is presumably true for man. Granted that a proper form of tourniquet is applied without excessive tension, the danger of gangrene under ordinary surgical conditions is largely imaginary. However, certain other sequelae are of surgical interest, particularly the occasional paralyses or contractures. Only two possible causes for such lesions exist: pressure in the zone of ligation and asphyxia. Experimental observations show that permanent paralyses arise only from direct pressure of the tourniquet and suggest that wide pressure is more injurious than a narrow band. The duration of the nerve paralyses increases in proportion to the time of ligation. The tension of the tourniquet and the temperature during ligation are important factors in the after-effects. Motor and sensory nerves differ in their sensitiveness to asphyxia in that the former suffer paralysis much more readily and also regenerate more slowly. Peripheral ganglion cells are much more resistant than the fibers of cerebral or spinal nerves.

**Sorbitol in Glaucoma**—In the twelve cases of glaucoma in which Bellows and his co-workers administered a chemically complex alcohol (sorbitol) of approximately the same molecular size as dextrose the intra-ocular tension was lowered. The greatest drop was obtained in patients with high intra-ocular tension who did not respond to the administration of miotics alone. Although a gradual decrease in tension was noted as early as two hours after the injection, in most cases the maximal effect was reached from twelve to twenty-four hours after injection. Then the tension gradually rose and reached a level approaching the original value, but in no instance did the tension rise appreciably above that point. In several instances in which operative procedures were not undertaken the intra-ocular tension observed for a number of days remained at a fairly normal level. In some cases repeated injections of sorbitol achieved a pronounced effect when a single injection had produced little change. The authors conclude that 100 cc of a 50 per cent solution administered intravenously and repeated in twenty-four hours, if necessary, will nearly always reduce intra-ocular tension when it is greatly increased and is not controlled by the use of miotics alone. It thus relieves the attending pain and prepares the eye for operation.

**Iodine Balance in Exophthalmic Goiter**—Puppel and Curtis state that three normal persons maintained on a low intake of iodine remained in continuous negative iodine balance. The blood iodine averaged 43 micrograms per hundred cubic centimeters. However, three patients with exophthalmic goiter maintained on a low intake of iodine similar to that of the normal persons showed a great increase in the excretion of iodine, particularly through the feces. This resulted in an increase in negative iodine balance of from two to three times the normal. The blood iodine was increased, averaging 9 micrograms per hundred cubic centimeters. The factors studied, which may influence the increased negative iodine balance of patients with exophthalmic goiter on a low intake of iodine, were the effect of general hospital management, roentgen therapy and thyroidectomy.

**Localized Outbreak of Poliomyelitis**—Somerville cites the histories of five cases of poliomyelitis occurring in a rural area. The first patient was a school teacher, showing, with other signs and symptoms, fairly definite loss of voice, with complete recovery. The four other patients were children attending the school, two of them showed definite paralysis, with complete recovery in one and partial recovery in the other. The spread appears to have been from the teacher to the pupils. The incubation periods varied from eight to fourteen days. One child, who did not show any paralysis but was definitely sick, appears to have been the source of infection for two other children twenty-one days after the onset of his symptoms. The exposure of these two patients apparently resulted from playing with the recovered child for an hour or two. In one of these two cases the incubation period was twelve days, with paralysis occurring in spite of serum being given twelve hours previously. In the other case the incubation period was eight days. This latter case did not show paralysis and was not notified as poliomyelitis.

**Silicotuberculosis**—Sweany describes the joint action of silicosis and tuberculosis. He does not consider silicotuberculosis as a disease entity but a "blend" in which every shade between the two conditions may be found as well as other associated peculiarities. He discusses only the principal types of the whole disease complex, from which he concludes that the whole field of silicotuberculosis seems to be related to three factors—silicosis, tuberculosis and inert dust. The sil-

cosis and tuberculosis enhance each other, the coal dust tends to check both but is prone to cause the development of huge masses and finally cavities. If the inert dusts predominate the fourth hazard appears, viz acute infection. The hazard of acute infection, however, is not in the same category as the silicotuberculosis or even the silicosis.

**"Antientdotoxic" Action of Sulfur Compounds**—Gross and his collaborators investigated the possible antientdotoxic action of sulfanilamide and of 4,4'-di-(acetylamino)-diphenylsulfone against meningococcus and hemolytic streptococcus endotoxins. In the experiments with meningococcus endotoxin two series of mice were employed, each consisting of ten controls, ten treated with sulfanilamide and ten treated with two minimal lethal doses of meningococcus endotoxin. All controls died in less than forty-five hours. While there was a slight increase in survival time of the sulfanilamide treated mice (average of about ten hours), all animals died in less than sixty-nine hours. In the sulfone treated group there was no increased survival time, but one mouse survived indefinitely. With one minimal lethal dose, eight out of ten controls died in twenty-seven hours, one in less than sixty-eight hours and one survived indefinitely. In the sulfanilamide treated group all ten mice died in less than forty-eight hours, while all ten sulfone treated animals died in less than twenty-six hours. The results therefore indicated no antientdotoxic action on the part of either drug against formaldehyde-killed meningococci. In the experiments with hemolytic streptococcus endotoxin a series of fourteen mice, eight of which had received 25 mg

of sulfanilamide orally one hour earlier, were given one minimal lethal dose (0.7 cc) of C 203 suspension of hemolytic streptococcus endotoxin intraperitoneally. The treated mice were subsequently given the same dose of sulfanilamide once daily. A second series of forty-five mice were given sublethal doses of the C 203 suspension, 0.1 cc on the first day, 0.2 cc on the third day and 0.5 cc on the ninth day. Fifteen of these animals were untreated, fifteen were treated orally once daily with 25 mg of sulfanilamide and the other fifteen were similarly treated with 25 mg of 4,4'-di-(acetylamino)-diphenylsulfone. In the first series all eight treated mice died within ninety-six hours. Of the six control mice four died within fifty-three hours, one on the fourth and the last on the eighth day. Cultures of the peritoneal exudates were sterile. In the second series, involving the use of multiple sublethal doses, there were three deaths in the untreated control group within fifteen days, while the sulfanilamide-treated group had five and the sulfone treated group six deaths. Sulfanilamide therefore showed no antientdotoxic action against single lethal or multiple sublethal doses of hemolytic streptococcus endotoxin. Similarly, 4,4'-di-(acetylamino)-diphenylsulfone exhibited no antientdotoxic action against multiple sublethal doses of killed hemolytic streptococci.

**Prophylactic Serums and Vaccines in Dysentery**—In an attempt to formulate a rational scientific basis for the use of prophylactic serum and vaccine Felsen and Osofsky determined the effect of the simultaneous injection of *Bacillus dysenteriae* and serum, the injection of serum at varying periods after inoculation with *Bacillus dysenteriae* and the injection of anti-dysentery serum at varying intervals before inoculation with *Bacillus dysenteriae*. Immune rabbit serums protected mice against ten lethal doses of a moderately virulent strain of *Bacillus dysenteriae*. This protection was evinced when the protective serums were injected previously to or together with the inoculation of the organism. When the serum injection followed the fatal dose of bacteria, no protection could be observed. Active immunization produced by the use of vaccine also offered a considerable degree of protection.

**Bacteriology of Normal Skin**—Price describes a method for studying the bacteriology of the normal skin and shows the effect of mechanical cleansing on the flora of the skin. The underlying principle of the test is simple. If hands are washed in a basin of sterile water, a large number of bacteria will be removed. By plating and culturing measured specimens of the water, counting the colonies and multiplying them by the total volume of the water the exact number of bacteria removed can be calculated. Therefore, if a long series of basins is used and the hands and arms are scrubbed in each one in turn for the same length of time in a uniform manner, the washing in each basin will be found to contain progressively decreasing numbers of bacteria. Cumulative totals of organisms in these basins, therefore, when plotted against time, form a curve. This is a regular logarithmic curve which can be projected mathematically to zero. Bacteriologically, the most important variable factor in mechanical cleansing is the vigor used in scrubbing—or, more accurately, the amount of friction produced at the surface. Rinsing without friction has practically no effect on the resident flora. Washing by rubbing the hands together is far less effective than scrubbing with a brush. A soft brush is less efficient than a stiff one. Vigorous scrubbing of the hands removes germs much more rapidly than languid scrubbing. In the preoperative scrub-up the aim should be to remove the dirt, fats and transient bacteria. To accomplish this the nails should be trimmed short and scraped carefully to remove all visible dirt and then the hands should be scrubbed conscientiously for seven minutes (on the average), with warm (city) tap water abundant soap, a brush of medium stiffness with well packed bristles of equal length. The scrub-up will remove about half of the resident flora. Further reduction of that flora is best accomplished by means of chemical disinfectants. When gloves are changed between operations, there is no need to scrub the hands unless they have become contaminated when only two or three minutes is required. Beneath the gloves the resident flora will have increased, however, so use of a germicide

between operations becomes necessary. After reduction (e. g. by disinfection) reestablishment of the resident flora appears to proceed at a rate represented in general by a sigmoid curve. Hands and arms thoroughly degermed may require a week or more for complete reestablishment of the usual flora. Beneath clothing the generation time is slightly shorter. Under sterile rubber gloves it is much shorter, the existing flora increasing rapidly until it may exceed by far the ordinary flora. Transients lie free on the surface or are loosely attached along with the dirt by fats, hence they are removed or killed with comparative ease. Resident bacteria are more firmly attached and are far more resistant to attack by either detergents or germicides. The transient flora may contain any number of pathogenic bacteria, the resident flora relatively few as a rule. Certain contaminating organisms seem able to change status and become permanent residents of the skin. Consequently, prolonged or frequent exposure of the skin to contaminations may result in a resident flora containing many pathogenic germs. Such skin is not easily disinfected. Hands may thus become chronic carriers of virulent organisms.

**Unequal Nares as Diagnostic Aid.**—Leiner states that the presence of unequal nares has proved of value either as a single or as a confirmatory sign in the diagnosis of supranuclear, nuclear or peripheral nerve lesions involving the facial nerve. Its greatest value is found when diagnostic signs are of urgent necessity, i. e. when the patient is unconscious and in hemiplegia. The absence of this sign has its significance in malingerers. Study of the pathologic nares shows a falling in of the delicate ala on the side involved, often revealing a total collapse of this structure comparable to the dilated contour of the normal side. This complete collapse is viewed in nuclear and peripheral nerve involvement. In supranuclear lesions, inspection of both sides will show at a glance the side involved, which is not only narrower, but the pear shaped contour has disappeared and the position of the ala has shifted, while the normal ala retains all its characteristics. In fractures of the base of the skull in which the middle fossa is involved, particularly when the fracture extends through the mastoid and aqueduct, an inspection of the nares in unconscious patients showed a total collapse of the nares on the side involved. In the refrigerating type of Bell's palsy, cases are seen in which the entire nose is pulled over to one side.

\*Pulmonary Tuberculosis in Old People. M. H. Joress. Boston.—p. 885.

**Pulmonary Tuberculosis in Old People.**—Joress studied the signs and symptoms of sixty unselected elderly patients with pulmonary tuberculosis. Thirty patients presented caseation besides fibrosis, twenty-four of whom had cavities. The latter group presents a definite variance from the generally accepted concept that tuberculosis of senescence is of the chronic fibroid variety, with the implication that the lesions are benign. Likewise, contrary to general opinion, in more than one third of the patients the disease was manifested by an acute onset. The seriousness of tuberculosis can further be attested by the occurrence of hemorrhage in ten patients. Night sweats occurred in ten and fever in twelve. No apical rales were elicited in twenty-four, while twelve showed signs

of cavity and twenty-six patients showed cavernous disease on roentgenographic examination. The sputum was positive in twenty-three among the fifty-two patients in whom it was examined. Of the fifty-two properly followed patients, about one half improved and one half did not. Of the twenty-nine patients who "improved," eighteen belonged to the latent apical and chronic fibroid types and only eleven were fibrocavitary. In the group designated as "worse" there were one latent apical, two chronic fibroid and three fibrocavitary cases at the beginning of the observation period.

The Mechanism Which Controls Hydrogen Ion Concentration of the Body Fluids. Suggestions in Practical Therapy. A. W. Oelgoetz. P. A. Oelgoetz and J. Wittekind. Columbus.—p. 1362.

**Infections of the Hand.**—Koch warns that the successful treatment of infections of the hand does not consist simply in the administration of some new drug three times a day or the daily injection of a new and widely advertised pharmaceutical product. If these infections are to be treated successfully one must still adhere to well recognized surgical principles, many of them as old as surgery itself, and many of them disregarded from time to time in the unsuccessful effort to find a short cut to successful treatment. Whether an infection involves the hand or some other part of the body, the questions presenting themselves are whether (1) the infection is an acute spreading process or is localized, (2) what tissues and structures are involved, (3) how an infection involving these tissues can be drained efficiently and with a minimal risk of injury, (4) what should be done after drainage has been secured and (5) what type of infection is present and what organisms are responsible. The author states that the surgeon who keeps constantly in mind the possibility of unusual infections and does not delay in securing both anaerobic and aerobic cultures and in making serologic tests when an infection presents unusual symptoms or is unduly persistent does both himself and his patient a service.

**Endemic Typhus in Animals.**—Brigham points out that the animals native to the United States which have been previously reported to be susceptible to endemic typhus fever are the woodchuck, meadow mouse, whitefooted mouse, opossum, old field mouse, cotton mouse, golden mouse, wood rat, cotton rat, rice rat and flying squirrels. Raccoons were found insusceptible. He states that further studies now add to this list two species of squirrels, two species of wild rabbits, a species of chipmunk and the skunk. Two gray foxes were not susceptible. No strains of typhus recovered from these animals exhibited any differences, when compared in guinea pigs, from the original Wilmington strain of endemic typhus.

**Nicotinic Acid as Prophylactic in Pellagra**—In an effort to determine whether pellagrins would remain free from diagnostic evidence of pellagra if treatment with nicotinic acid was directed individually, Spies and his colleagues followed up 694 pellagrins examined in 1936. The present status of all patients was determined and plans for their study in prevention or treatment groups were made. After the initial examination most of the patients returned to the clinic at least once a week for examination, some more often. Each patient was treated individually and was given a week's supply of nicotinic acid in 100 mg tablets. The dosage was adjusted individually. The patients continued their usually grossly inadequate, unbalanced diets. The prevention group was made up of 199 persons in whom pellagra had occurred at least once every year for the last two to fifteen years. Of these, 173 received nicotinic acid. As the season advanced it usually became necessary to increase the initial dosage. Infections, unusually strenuous exercise or an extremely inadequate diet tended to necessitate an increased dosage of nicotinic acid. There was in every case an almost immediate increase in sense of well being and vigor likewise indigestion, nausea and diarrhea were relieved. Constipation, when it persisted after general improvement, usually responded favorably to an increased dosage of nicotinic acid. Nervousness, irritability, headache, insomnia and mental confusion responded quickly to adequate dosage. It was almost universally volunteered by the patients that their skin became lighter and that the vague burning sensations in various parts of the body disappeared soon after treatment was initiated. Although their general condition improved, in a number of these patients polyneuritis developed, but clinically active pellagra did not develop in any. The polyneuritis persisted until adequate vitamin B<sub>1</sub> therapy was given. Patients of this group who were without the drug from one to two weeks experienced, within a week, a recurrence of their symptoms of subclinical pellagra. Without exception they resumed treatment with benefit similar to that previously experienced. The twenty-six persons who served as a control group had a recur-

rence of the disease. In twenty of thirty-four patients in a second control group in whom a history of yearly relapse in the past was indefinite, diagnostic evidence of the disease developed. Of 321 patients with clinically active pellagra treated, 291 were not hospitalized. In many of the ambulatory patients the disease was so severe that hospitalization would formerly have been required. In each of the ambulatory pellagrins treated there was a prompt and beneficial response following adequate nicotinic acid therapy. Of the hospitalized patients three died of other diseases at a time when the pellagra had been cured or was improving. No patient died of uncomplicated pellagra. For patients with acute pellagra in relapse, nicotinic acid is perhaps best given in 50 mg doses ten times a day by mouth, even if the patient is vomiting. Nicotinic acid is not a substitute for all the essential nutritional substances usually missing from the pellagrins' diet. A liberal and well balanced diet must be urged. Within twenty-four hours after nicotinic acid therapy was begun the brilliant fiery redness and swelling of the tongue had disappeared, the greatly increased salivation had become normal and there was less discomfort of the oral mucosa. The associated Vincent's infection healed quickly. Similar changes took place whenever the mucous membranes were involved. Disturbed gastrointestinal function became normal soon after nicotinic acid therapy was begun. Acute mental symptoms, varying from slight confusion to delirium and mania, responded dramatically, in most cases overnight. In contrast nicotinic acid has been of no benefit in cases of psychoses and psychoneuroses unrelated to pellagra. The fiery red dermal lesions of all patients blanched following administration of the drug, but nicotinic acid seemed to have less effect when the continuity of the skin was broken and the lesions were moist, ulcerated, dry or pigmented. Nicotinic acid relieves only a deficiency of nicotinic acid or closely related substances. Its greatest value comes when it is added to a full, well balanced diet.

**Mechanical Treatment of Venomous Bites**—Allen discusses the possibilities and limitations of different procedures used for practical treatment of snake bite. 1 Many snake bites are nonfatal, especially when the quantity of injected venom is small, and recovery occurs in such cases without treatment or often in spite of wrong treatment. 2 Antivenin is recognized as the best and surest protection when the specific type of serum is promptly available. Doubts still exist as to whether it is sufficient and infallible in the most severe cases. Other treatment should probably be used. 3 The Jackson suction method is evidently valuable, but the necessary apparatus and the services of a physician for some ten hours must be available. 4 Timid excision is practically useless. Dangerous cases may be helped by reasonably early excision of a mass of tissue such as is commonly removed in a carbuncle operation. This plan may also be promising for smaller bites, such as those of the black widow spider. In a sufficiently desperate emergency excision can be performed by an unskilled person. 5 For the most overwhelming venom doses, such as may be typified by the bite of a king cobra, it is possible that excision and even antivenin may be insufficient. Experimental evidence indicates that amputation can prevent all dangerous symptoms, and in a case of sufficient danger the limb should obviously be sacrificed early in order to save life. 6 A tourniquet should be applied to stop circulation only for controlling hemorrhage during or after excision or amputation, for gaining time preliminary to amputation and in connection with local refrigeration. 7 Local refrigeration can abolish pain, stop toxic absorption and preserve the local tissues. These benefits are not lasting, and the only demonstrated value of the method seems to be as preliminary to amputation or for anesthesia. Local refrigeration offers a means of gaining time until antivenin can be obtained in the case of venoms which are not so powerfully proteolytic as the Crotalus group. Simple training in first aid methods of those most likely to be bitten can reduce the mortality in non-serum treated cases practically as near to the vanishing point as in serum treated cases, though the suffering and disability will be greater. The laborers and others who are mostly exposed to snake bites will generally carry out first aid with a hardihood which will atone for any lack of skill.

**Infertility and Sterility**—Stein bases his remarks on an analysis of 200 childless couples examined in private practice. Infertility was encountered in 103 matings as against ninety-seven sterile matings. In a former series there were fifty-seven infertile and 243 sterile couples. In both groups, primary infertility or sterility occurred about three times as frequently as did secondary. Uterine hypoplasia, tubal obstruction, previous abortion and chronic endocervicitis continue to play a significant part. The male partner is shown to be directly responsible in slightly more than one third of the cases of sterility and substandard sperm specimens were not infrequently revealed among the infertilities. Tubal patency tests were done in 111 cases. Tubal obstruction was encountered in twenty, of which fifteen were complete and five partial. Surgical measures were carried out in seventy-three cases. Pregnancies occurred in fifty-one of the infertile and in fifteen of the sterile matings. From this it is apparent that a considerable proportion of the matings were only relatively infertile. If given time, a certain proportion of apparently infertile women eventually succeed in becoming pregnant without investigation or treatment, as occurred in nine patients in this series. On the other hand, pregnancy is often delayed for an indefinite time among couples apparently healthy, even though no contraceptive is used and an investigation is urgently requested by them. In others, pregnancy follows immediately after the Huhner and patency tests are performed and before any other treatment becomes indicated. This fact strengthens the author's belief that the patency test with gas or with opaque mediums has therapeutic as well as diagnostic value. Glandular therapy played but a small part, its chief virtue resting in thyroid extract. Estrogenic preparations were used in the treatment of hypoplasia, and pregnancy sometimes occurred despite little change in the size of the uterus. The hormone now available from the serum of pregnant mares has been shown to stimulate ovulation in the human being and it is highly probable that this agent will prove of practical value in certain types of sterility. Favorable results should be expected from such therapy in minor grades of hypoplasia associated with immature or inactive ovaries and in cases of anovulatory bleeding. When the ovaries have become polycystic, however, no result can be expected from endocrine therapy. Surgery is then indicated.

**Swelling of Arm After Breast Amputation**—Since his recent article on the venographic observations in twenty cases of swelling of the arm following radical removal of the breast, Veal has seen twenty-six additional cases, a total of forty-six cases of swelling following operation. Twenty-two patients who did not experience swelling of the arm after operation have

been studied in order to determine the possible extent of venous obstruction that may exist before edema occurs. Venographic studies supplemented with venous pressure determinations have proved valuable as a means of differentiating between the several forms of swelling (venous, lymphatic and lymphatic and venous) of the arm following radical amputation of the breast. Simple lymphatic edema is the least frequent cause of swelling of the arm after such an amputation. This form of edema may result from recurrent lymphangitis cellulitis or cutaneous metastases. The deep veins of the arm are not primarily involved and remain patent. Edema resulting from obstruction of the axillary and subclavian veins is by far the most common cause of swelling of the arm following operation. The most frequent cause of the venous obstruction is a recurrence of the malignant growth along the course of these veins. In some cases the venous occlusion results from benign scar formation. In others the axillary vein is occluded by the sharp angulation of its course when the arm is dependent because of the fixation of the floor of the axilla. The venous obstruction produces a local increase in the venous pressure and fluid escapes into the tissues. Lymphatic stasis is a secondary result of the venous obstruction and if prolonged will lead to permanent blockage of the lymphatic flow. Infection is prone to develop and may lead to further obstruction and cause a greater degree of swelling. The skin may then become thickened and present the typical picture of lymphatic edema.

**Refrigerated Cartilage Isografts**—For the last five years in the reconstruction of contour defects of the face and its appendages O'Connor and Pierce have used "refrigerated cartilage isograft." The cartilage, mainly rib, is obtained under sterile or unsterile conditions and stripped of its perichondrium. It is thoroughly washed with ordinary tap water to remove any blood which may have collected on the cartilage. This material is then placed for at least one week before use in a covered sterile glass container and covered with a solution of one part aqueous merthiolate (1:1,000) to four parts of sterile physiologic solution of sodium chloride. The solution should completely cover all of the cartilage by at least 1 inch. The container is placed in the refrigerator and left there; it is taken out only when the solution has to be changed, cultured or the refrigerated cartilage used for grafting purposes. When new material is prepared the solution is drained off and changed twice a week for two weeks and then only once a week thereafter. Refrigerated cartilage isografts that have been preserved for more than six months are just as efficient as fresh cartilage. This long waiting period, although not advisable, does not materially affect the cartilage as a graft. Of the 375 transplants that the authors performed, local infection developed in six cases. This occurred mostly in grafts that were used to reconstruct the nasal bridge or tip in which external sterilization is difficult. These infections responded to local treatment with all the grafts remaining in situ except any portion of a graft that became exposed. The exposed portion of the graft was gradually digested or was surgically excised to speed up wound closure. The latter treatment was the usual procedure, as it materially shortened the postoperative care. If a refrigerated cartilage isograft becomes infected, the whole cartilage graft may be removed immediately. The infection generally subsides rapidly and the wound heals in a short time. If, in infection, good dependent drainage is established, the graft can be left in situ and it will survive, but healing will be delayed. Refrigerated cartilage isografts are the material of choice for certain types of contour reconstruction, as they are easy to obtain, will keep in vitro indefinitely, will not absorb, will resist infection, are pliable, are easily sterilized and will lend themselves favorably to sculpturing.

**Cinchona Febrifuge in Malaria**—Gore has commenced the use of cinchona febrifuge tablets in place of quinine and has found it to be a success not only in ridding the patients of fever but in preventing relapses and definitely reducing enlarged spleens. The drug also has a laxative effect. Among rural populations suffering from malaria the author's experience suggests that cinchona febrifuge powder should be the drug of choice. Honey is a good vehicle for making pills or paste and since honey is available in villages, 4 grain (0.26 Gm.) pills can be made with it for adults, and for children a proportionate quantity can be made into a paste with honey. As cinchona febrifuge is efficacious and cheap it will ensure the greatest benefit, as continuous treatment is more likely. Since 1916 the author gave as a routine a 3 grain (0.2 Gm.) dose of quinine hydrochloride at the commencement of the rigor, with the idea that fresh parasites in the plasma before entering erythrocytes would be killed in greater numbers, as quinine is absorbed rapidly. This single preliminary additional dose of quinine gave better results than cinchona febrifuge without it.

**Blood Supply of Abnormal Tissues in the Lungs**—Wright injected lungs from human cadavers in order to show the distribution of the pulmonary and bronchial arteries and their branches in pathologic lesions. He found that proliferative tuberculous lesions and actively growing chorionic carcinomas are avascular. The fibrous scars of tuberculous and silicotic lesions have vessels injected from the bronchial artery. The vessels which develop in fibrosarcomas growing in the lungs are all injected from the bronchial arteries. The vessels of the stroma of carcinomas growing in the lung are

injected from the bronchial arteries. The author's conclusion is that if in the adult lung a tissue develops which is usually supplied from the systemic arterial circulation, the vessels which grow with it are injected from the bronchial artery. This development of new vessels from the systemic arteries may be closely linked with the excitation of collagenous tissue to further development, irrespective of the nature of the causative agent of the collagenous proliferation.

**Red Cell Fragility**—Cassells investigated the erythrocyte fragility in various blood disorders in order to determine the character of the red cell fragility curve in different types of anemia and how far any observed change in the curve could be accounted for by the degree of anemia present or by other recognized changes in red cell characteristics. He found that the majority of anemias show a "shift to the left" of the curve of erythrocyte hemolysis in hypotonic saline solution. The curve tends to move to the right as the anemia improves. The shift to the left is dependent to some extent on the degree of anemia but not entirely, since correction for the anemia does not necessarily cause a return of the curve to normal limits. Some anemias, particularly those associated with pregnancy, fall within normal limits or their curve of fragility lies at the extreme right of the normal. (1) these cases show microcytosis and usually a higher color index, though the latter is not the determining factor, since cases of pernicious anemia have a curve to the left of normal and (2) the cells are not necessarily thicker than normal. In the absence of anemia the curve, following splenectomy, is shifted to the left. The only other abnormality in such cases is a tendency to macrocytosis.

**Meningo-Encephalitis Due to *Cryptococcus Meningitidis***—Greenfield and his associates cite a fatal case of meningo-encephalitis due to *Cryptococcus meningitidis* (Torula histolytica). The organism possibly gained entry through the broken skin. The diagnosis in this case and in other recorded cases was not made until after death. The symptoms of this disease closely resemble those of tuberculous meningitis and cerebral tumor and abscess. In doubtful cases of chronic meningitis the cerebrospinal fluid should be examined with the oil immersion objective and injected intracisternally into laboratory animals. Of the many names applied to this organism the name *Cryptococcus meningitidis* suggested by Dodge is recommended as the most suitable.

**Treatment of Lobar Pneumonia with Sulfapyridine**—Dyke and Reid used sulfapyridine in the treatment of eight cases of pneumonia of the lobar type. The pneumococcus was typed in every case by mouse inoculation. Treatment was commenced from twelve hours to four days from the onset of the pneumonia. An immediate fall of temperature, pulse rate and improvement in the clinical condition followed the administration of the drug in every case. In all cases in which the drug was administered in full and efficient dosage (sufficient dosage for the adult appears to be 2 Gm followed by 1 Gm every four hours for five doses and then 1 Gm every six hours) the subsequent course was uneventful and recovery rapid. Serum and all other forms of treatment other than symptomatic were withheld. The drug should be given for at least five days.

**Pentothal with Nitrous Oxide and Oxygen**—Organe and Broad used pentothal combined with nitrous oxide and oxygen anesthesia in 236 cases. Operations performed include tonsillectomy and orthopedic, gynecologic, perineal and rectal operations. Vomiting was greatly reduced and the condition of the patients was better than after any other form of general anesthesia. The only immediate advantages to the surgeon are the rapid induction of anesthesia and the quiet breathing for abdominal operations. The method is popular with patients because of the pleasant induction and recovery compared with other forms of anesthesia. Nursing is easier because there is little vomiting or restlessness and no breathing difficulty. This combination of anesthesia should be attempted only by anesthesiologists who are already familiar with the use of pentothal. The technical complications are that during anesthesia the needle may become blocked or slip out of the vein. In these circumstances it is necessary to make a fresh venipuncture. A few patients complained of sore arms after operation and in two cases there was thrombosis of the vein. On three occasions a needle was broken in the arm.

Economic Aspect of Industrial Surgery J. C. B. Allen—p. 825

**Hematocrit Determinations in Blood**—McLern found that mean corpuscular volume ranged in his sixteen patients suffering from hyperchromic macrocytic anemia from 114 to 170 cubic microns, the average value being 138 cubic microns, the mean corpuscular hemoglobin ranged from 38 to 58 micro-micrograms, the average value being 47 micro-micrograms, the mean corpuscular hemoglobin concentration ranged from 29 to 45 per cent, the average value being 35 per cent. The high mean corpuscular volume and mean corpuscular hemoglobin, which are well above the normal values, are the characteristic features of this type of anemia. The mean corpuscular volume in fifteen cases of hypochromic anemia ranged from 62 to 81 cubic microns, the mean value being 73 cubic microns, the mean corpuscular hemoglobin ranged from 13 to 21 micro-micrograms, the mean value being 17 micro-micrograms, the mean corpuscular hemoglobin concentration ranged from 17 to 27 per cent, the mean value being 22 per cent. The low values for mean corpuscular hemoglobin and mean corpuscular hemoglobin concentration are the characteristic features of the group. The mean corpuscular volume in two of three cases of acholuric jaundice fell within normal limits. In acholuric jaundice the mean diameter of the red cells is less than normal. The observation that the corpuscular volume is usually within normal limits is explained by an abnormal globular shape of the erythrocytes. This is termed spherocytosis and is regarded by Haden and others as the fundamental variation from normal in the disease. The mean corpuscular volume in three cases of polycythemia was within normal limits. The mean corpuscular hemoglobin and mean corpuscular hemoglobin concentration were slightly below normal in two of the cases. In fifty-five normal Melbourne residents, values for mean corpuscular volume, mean corpuscular hemoglobin and mean corpuscular hemoglobin concentration were substantially the same as the values obtained in America and England. The method is recommended as a ready means of differentiating between hyperchromic macrocytic and hypochromic microcytic anemias.

Investigations on Sclerosis of Pulmonary Artery and Its Branches

S. Ciechanowski—p. 365

**Hypertensive Syndrome in Acute Nephritis of Childhood**—Debre and his associates point out that, although the existence of arterial hypertension in the course of acute nephritis of childhood is known, it is habitually ignored. They call attention to the frequency of hypertension in acute nephritis of childhood and emphasize that the physician who suspects, recognizes or treats acute nephritis in a child must watch for it every day. They emphasize the importance of the complications that may be caused by the arterial hypertension of acute nephritis. They give special attention to the cardiac and nervous disturbances. The authors studied twenty-three children ranging in age from 12 to 14 years. They believe that infections of the upper respiratory tract are most often responsible for the nephritis. The onset with lumbar pains and sudden increase in temperature, so frequent in adults, is not common in children. Occasionally the first sign is a hematuria (three of the twenty-three cases) and often it is a malleolar or palpebral edema (ten cases), appearing insidiously in the course of general disorders such as pallor, asthma and anorexia with or without vomiting. They discuss the cardiac rhythm, the hepatic and pulmonary forms of asystole and acute pulmonary edema. Cardiac disorders frequently appear when the arterial tension is high and their evolution parallels that of the hypertension. The nervous disorders resulting from the arterial hypertension in children with acute nephritis are especially eclampsia and amaurosis. Factors indicating a favorable prognosis are early onset of treatment, short duration of the causal infection and slight increase in arterial tension. Severe changes in the urine and blood indicate an unfavorable prognosis. For treatment they regard a dry diet as the best and recommend a regimen with a high carbohydrate content and a low fluid intake.

**Osteomyelitis During Growth**—Fevre criticizes the use of the term osteomyelitis of adolescence, which he says is usually applied improperly and then gives his attention to the classical osteomyelitis of childhood. Discussing the advisability and the choice of the time for an intervention, he says that it is not necessary to intervene during the primary septicemic forms of osteomyelitis, for all interventions during this stage are locally ineffective and they may be dangerous. It is necessary to wait with the intervention so that a well localized suppurating focus exists. The local signs are more reliable than the general signs in ascertaining the existence of pus. In the frankly acute cases of osteomyelitis, the time of intervention must be neither too early nor too late. For a long time he employed reduction by simple continuous extension in osteomyelitic luxations of the hip. Naturally it was often necessary to open the abscess, but contrary to the general opinion he never thought it necessary to do more. The author stresses further that in some cases of sudden aggravation an intervention is urgent when signs of a duly localized focus exist. In this connection he recalls cases in which a retarded intervention made a secondary operation necessary. On the determination of the nature of the intervention the author adheres to the principle of trying to adapt the operation to the existing lesions. That is why frequently his interventions are restricted to the opening of the abscess and that the pri-

mary operation terminates only exceptionally in a trepanation or a resection. If the general condition is not improved by the opening of the abscess or if its alteration seems to be secondary to osseous lesions of the focus, he resorts to trepanation or resection. Local immobilization, usually by means of a plaster cast, and a general treatment which is adapted to the circumstances and to the clinical aspects of the osteomyelitis precede and complete the surgical treatment.

**Treatment of Pneumonia by p-Aminophenylsulfamide**  
—Cam and his associates say that it is generally admitted that the organic compounds of sulfur and especially p-aminophenylsulfamide are experimentally active against pneumococcal infections. It has been demonstrated that this chemotherapy is capable of protecting mice that are inoculated with virulent strains of pneumococci and that it has a correspondent bactericidal action in vitro. However, little is known about the clinical application. To be sure, Heintzelman and his collaborators reported in 1937 about favorable results with p-aminophenylsulfamide in pneumonia patients with type 3 pneumococcus (*Am J M Sc* 193 759 [June] 1937, abstr. THE JOURNAL, July 31, 1937, p. 389) and suggested that sulfanilamide therapy deserved wide application in the treatment of human pneumonias. Cam and his associates employed it in the treatment of a number of patients with pneumonia, some of whom were alcoholic addicts and some of whom were quite old. They describe the clinical histories of eight cases and say that they eliminated from this report several cases of influenza in the course of which auscultation revealed pulmonary rales and rapid recovery occurred under the influence of chemotherapy. Discussing the dosage of p-aminophenylsulfamide, they say that they administered 3 or 4 Gm daily, depending on the nature of the case. They always administered this considerable amount until the temperature returned to normal, then they reduced it to 2 Gm and then to 1 Gm for several days following the defervescence. They do not believe that it was pure coincidence that the pneumonic foci disappeared during the medication with sulfanilamide. The grave and even hopeless condition of some of the cases makes that appear unlikely. Moreover, the defervescence and the improvement of the general and functional conditions followed so rapidly after the onset of the treatment that a relationship of cause and effect cannot be denied. Regarding the dangers of sulfanilamide therapy, the authors say that they are negligible because the treatment does not have to be continued for long. In their cases, which were for the most part grave, they noted only a more or less intense cyanosis, which always disappeared after the cessation of the medication, they did not observe renal impairment. They do not draw definite conclusions from their observations but think that the near future will tell whether the treatment of pneumonia will make the same progress as that of erysipelas.

- \*Nontropical Sprue Study of Four Cases Observed in Belgium L. Brull A. Lambrechts and G. Brac —p 457

**Nontropical Sprue**—The object of this extensive report by Brull and his associates is to describe their investigations in four cases of chronic diarrhea, which are characterized by steatorrhea, a large deficit in the intestinal absorption of calcium and phosphorus and a demineralization, which is evident

in generalized osteoporosis, hypocalcemia and severe tetany. Associated in variable degrees with these cardinal symptoms are denutrition, meteorism, anemia, disturbances in cutaneous pigmentation, hydremia and edemas. These cases recall disorders described under the term nontropical sprue, celiac disease of adults or idiopathic steatorrhea. The principal symptom is the steatorrhea. The nonabsorption of the lipids leads to the appearance in the feces of considerable amounts of unassimilated calcic soaps, a phenomenon which is probably the basis of the decalcification and of all the ensuing symptoms. On close analysis the syndrome appears to be a condition of complex avitaminosis. The encouraging results obtained by the authors with vitamin B<sub>2</sub> (riboflavin) support the hypothesis according to which this steatorrhea depends on a B<sub>2</sub> avitaminosis. The decalcification connected with the steatorrhea must be of the same origin. The melanoderma disappears after treatment with lemon juice or by a regimen that is rich in hydrosoluble vitamins. The anemia is corrected by the antianemic factor of the liver. The disorder in the phosphorus metabolism, which consists in the predominance of the fecal excretion over the urinary elimination, is promptly counteracted by vitamin D. The deficiency of vitamin A in the plasma is restored to normal by the administration of this vitamin. These deficiencies are not primary. These patients have a more or less generalized deficiency in the digestive secretions such as pepsin, hydrochloric acid, bile salts and lipase, which indicate a functional impairment of the digestive tract. It seems that it is this impairment which reduces the absorption not only of the lipids but also of the vitamins. Thus the complex hypovitaminosis is secondary to a disorder of the digestive tract. In studies on the mineral metabolism the authors demonstrated that vitamin D favors the intestinal absorption of phosphorus and that the metabolism of the lipids and of calcium are interdependent. They further showed the respective merits of various methods of therapeutic recalcification, notably the uselessness of recalcification by the parenteral route. With regard to the treatment they stress the following points: 1. No alimentary restrictions must be imposed, except those on lipids. 2. The only factor which is likely to influence the absorption of lipids directly is vitamin B<sub>2</sub>, still its action demands more confirmation. 3. Multiple vitamin therapy is useful together with a generous diet. 4. Prolonged recalcification by mouth is helpful in counteracting the tetany and the osteoporosis. 5. Antianemic treatment is efficient. In short, the entire symptomatology can be counteracted, without however definitely counteracting the fundamental disorder, the tendency to steatorrhea.

Lingual Acrobatus E. Oppikofer —p 1207  
Trauma and Paralysis W. Moos —p 1208  
Conditions of Excitation in Acute Porphyria Two Cases Irene Ferrat Marton —p 1209

**Specific Agent of Tularemia**—Following remarks about the geographic distribution of tularemia in Europe, Galli-Valerio describes his studies on the causal agent of this disease. He says that it has been cultured on coagulated egg medium, on dextrose agar with blood and cystine and on other mediums. The medium of choice is dextrose agar with blood and cystine, on which it grows in abundant grayish colonies which have a smooth and slightly glossy surface and a wavy margin. The organism is strictly aerobic and it grows at a temperature of 36 or 37 degrees. It is absolutely gram negative but it is stained readily by diluted fuchsin of Ziehl, by the blue of Papanicolaou, by thymol, by Giemsa 1:20 and by eosin. It appears in all cultures under two completely intermingled forms: a micrococcus and a very short bacterium. The first of these two forms, the micrococcus, predominates. After describing his experiences in animal cultures the author gives his attention to the classification of the causal organism of tularemia. He says that different observers have placed it near the bacilli of hemorrhagic septicemia or the pest and pseudotuberculosis of rodents. This comparison seems entirely

erroneous to him and he classifies the organism as a coccobacterium, a type which he suggested in 1924 for the micro-organism of undulant fever and for the organism which causes abortion in bovine animals and which appears under the form of small, gram-negative cocci mixed with short rods. From the morphologic point of view these three micro organisms are quite analogous and, more interesting still, the serum of the patients affected with tularemia agglutinates not only the tularensis coccobacterium but often the melitensis coccobacterium and the abortus coccobacterium. American investigators observed that, of 100 tularemic serums, thirty-seven agglutinated also the melitensis coccobacterium and the abortus coccobacterium. Moreover, in three of eight patients with undulant fever the serum agglutinated the tularensis coccobacterium. However, the tularemic serums did not agglutinate the organisms of typhoid, paratyphoid, dysentery and so on. Thus the serologic reactions confirm completely the observations on the morphologic analogy of the three organisms. The term coccobacterium which the author applies to these organisms indicates their character in that the same culture contains coccus and bacterial forms. It is interesting to note that the three coccobacterial organisms (melitensis, abortus and tularensis) are transmitted to man by animals, namely by goats, cattle and rodents, respectively.

Clinical and Experimental Studies on Pathogenesis of Gastric and Duodenal Ulcer E Periti—p 473

**Hypochromic Anemia After Gastric Resection—Ojetti** observed the behavior of the blood and the gastric secretion and the stomach in a group of eighty one patients who had had a surgical intervention for gastroduodenal ulcer. The observations were made from one to eighteen years after the operation. All patients who had had ample resection of the Polya-Finsterer type (fifty-one) had anachlorhydria. The amount of hydrochloric acid in the gastric secretion was moderately diminished in the majority of the cases in which a moderate resection (six cases) or a conservative operation (twenty-four cases) had taken place. Nine patients in the group of those who had had an ample resection and seven in the group of those who had had a conservative operation showed either recurrence of the ulcer, which was verified by the roentgen examination of the stomach, or bloody stools. Therefore they were excluded from the group of the observations. Of the group of forty-two who had had an ample resection eight patients showed essential hypochromic anemia with figures of hemoglobin lower than 80 and erythrocytometry lower than 4,000,000. Two patients in the group of six who had had moderate resection showed moderate anemia. Anemia was not seen in the group of seventeen cases in which a conservative operation had been performed.

**Periosteal Bone Changes in Nurlings—Von Chiari** says that Erdheim's contention that the small amount of ore deposited at the sites of greatest mechanical wear is correct. The long tubular bones are exposed to the greatest strain at the periphery and here the calcification is most pronounced. It was pointed out by Davidson and Merit that the progressive osteoporosis of the long tubular bones in rickets is due to

the fact that the calcium salts are drawn away from the trabeculae and are deposited near the periosteum. These authors observed shadows along the periosteum of the tubular bones in the beginning of florid rickets, although other visible signs of rickets were absent. This sign of the displacement of calcium salts makes possible the early roentgenologic diagnosis of rickets, cases have been observed in which the appearance of the aforementioned roentgenologic signs preceded the appearance of the clinical signs of rickets. After citing the opinions of several investigators on the periosteal deposits that develop during rickets (rachitic osteophytes), the author points out that similar deposits, but with a greater calcium content, are observed in syphilitic infants. The periosteal deposits of rachitic or syphilitic origin have been discussed repeatedly, but he maintains that in addition to these there is yet a third type. Summarizing his observations in thirty-one cases of the latter type, he says that in these cases the periosteal deposits on the long tubular bones are symmetrical. No signs of syphilis are observed and the periosteal deposits differ in localization from the rachitic osteophytes. Moreover, rachitic osteophytes develop only in older children, whereas the periosteal deposits discussed here are observed in infants during the first six months of life. The author thinks that a reaction of the highly sensitive periosteum of young nurslings to inflammatory processes is probably the cause of this early form of periosteal deposits, because the anamnesis of the infants who showed these periosteal reactions often disclosed pyoderms. He stresses that Pehu's opinion that periosteal deposits are invariably indicative of syphilis must be rejected. On the other hand, he thinks that great caution is necessary in the evaluation of the periosteal deposits that are visible in the roentgenogram. Each case must be carefully observed in order to exclude syphilis. The cure of the periosteal reactions takes place without treatment in the course of two or three months.

Pernicious Anemia and Gastric Carcinoma as Stages of Chronic Gastritis W Haring—p 1586

**Brain-Lipoid Reaction in Schizophrenia—Jacobi** directs attention to the brain lipoid reaction on the cerebrospinal fluid of schizophrenic patients, which Lehmann-Facius described in 1936 and the reliability of which was corroborated by several others. After briefly reviewing the technic and the literature of this reaction, the author describes his own experiences with it on the cerebrospinal fluids of twenty-four patients with schizophrenia and twenty-four patients with various mental disorders such as manic-depressive insanity, arteriosclerosis, postencephalic conditions, senile dementia and epilepsy. On all cerebrospinal fluids the test was made two or three times. In one test the sediment was only mildly shaken (five or six times) by hand, in a second test it was shaken vigorously by hand (about twenty times) and finally a whole series of cerebrospinal fluids was shaken simultaneously in an apparatus by mechanical means. The author regarded this procedure as necessary, because he suspected that the outcome of the reaction was to a great extent dependent on the intensity with which the specimen was shaken. Further, he made control tests by employing quantities of physiologic solution of sodium chloride instead of the cerebrospinal fluid. In describing his results, he says that the flocculation was stronger when the amount of cerebrospinal fluid which had been added was smaller, and that at the second reading (after twenty four hours) the specimen showed stronger flocculation than at the first one. The same could be observed in the controls with physiologic solution of sodium chloride, although the reaction was perhaps somewhat weaker. It was never possible to base the diagnosis schizophrenia on the outcome of the reaction. The specimens that were shaken only a few times were all

positive, those which were shaken twenty times were negative, and those which were shaken in the apparatus were positive or negative, depending on the length of time they had been shaken. To be sure, occasionally there were slight differences in the intensity of the reaction. However, intense flocculation was observed not only in the cerebrospinal fluids of schizophrenic patients but also in those with epilepsy and other mental disorders. In many instances schizophrenia showed the lesser flocculation. On the basis of his observations the author reaches the conclusion that the Lehmann-Facijs brain-lipoid reaction on the cerebrospinal fluid is not suitable for the diagnosis of schizophrenia.

**Sedimentation Speed and Physical Exertion**—Deist made studies on 260 soldiers who had had sedentary occupations before their entry into military service and had not practiced athletics or sports. Thus these men were subject to considerable exertion in the change from their former mode of life. It is known that in the higher age groups the sedimentation speed is somewhat accelerated, but since the ages of these soldiers varied between 23 and 37 the author thinks that the age factor can be disregarded. The sedimentation speed of the men was tested during the first week of the service, four or five weeks after that, and again during the seventh week. The blood was withdrawn between 7 and 8 o'clock in the morning, before breakfast. The sedimentation speed was determined according to the original Westergren method. Of the 260 men, 220 (84.6 per cent) showed a normal sedimentation speed in all three tests. The others had an increased sedimentation speed in all three in two or in only one of the tests. In some of these the deviation from the normal sedimentation values could be explained by intercurrent diseases such as febrile catarrhs of the upper respiratory tract, lymphangitis, extravasations or effusions. In two of the soldiers in whom all three tests showed an increase in the sedimentation speed neither a thorough examination nor the anamnesis revealed anything that would explain the increased sedimentation speed. In twelve men in whom only the second sedimentation test showed an increase no explanation could be found for the temporary acceleration and it is possible that the unaccustomed physical exertion might be a factor. The same might also be true in the aforementioned two cases. However, even if the physical exertion should be the causal factor of the increased sedimentation speed in fourteen of 260 cases, in view of so small a proportion (5.4 per cent) it cannot be said that physical exertion regularly influences the sedimentation speed. Consequently the author thinks that a negative answer must be given to the question regarding the influence of physical exertion on the sedimentation speed.

**Serum Cholesterol in Rheumatic Disorders**—Knuchel determined the total, the free and the esterified cholesterol in patients with various types of rheumatic disorders. The results of these tests are recorded in tables. Summarizing his observations, he says that the greater the tendency is to exudative changes in rheumatic disorders, the lower is the cholesterol content, particularly the esterified cholesterol. It has not been determined as yet whether the reduction in the cholesterol values is a cause or one of the prerequisites for the development of rheumatic disorders, or whether it is only an accompanying symptom in that, in the presence of an increased amount of toxins, the organism consumes more cholesterol. If a normal cholesterol content is regarded as an indication of a normal defense power, it must be concluded that in rheumatic diseases the defense mechanism is more or less impaired. This corresponds with other clinical and serologic (comple-

ment content) observations. In attempts to explain the mechanism of Weltmann's coagulation band, the impression was gained that a second factor, perhaps the lecithin content, plays a part. Extractions that were made in the course of the studies on the coagulation band induced the author to determine the cholesterol value of the serum before and after chloroform extraction. He found that the closer the cholesterol values are to the normal ones the greater is the component of cholesterol that is dissolved in chloroform, and that this component decreases in the presence of subnormal values. In the latter cases a chloroform soluble cholesterol component may be entirely absent. The author thinks that it is premature to draw final conclusions from these observations, nevertheless he assumes that the antitoxic component of the serum cholesterol is especially soluble in chloroform and that if it could thus be differentiated from the remaining cholesterol this method might prove valuable in the determination of the defense powers of the organism.

**Electrocardiogram in Cardiac Diseases**—Schulz points out that electrocardiograms of the same person, when made with different apparatus, will show different forms. The author describes his observations on 100 persons ranging in age from 8 to 49 years, the majority being near 20 years of age. None of them had a history of heart disease. They were subjected to electrocardiographic tests during rest and again after exertion. The author says that a negative, an isoelectric or a flat course of the T wave in lead 3 has no pathologic significance. To be sure, if such deviations occur in the first two leads or in all three leads they must be regarded as more serious. He further discusses the changes in the QRS complex, pointing out that a prolongation of this complex after exertion has been regarded as pathognomonic for myocarditis. From observations on his own material he concludes that if this phenomenon occurs in at least two leads it seems to be of pathologic significance. Further he gives his attention to the normal U wave, a little known sixth deflection, in the electrocardiogram. According to some investigators this wave is present in all normal electrocardiograms, chiefly in the second lead. The author observed it in forty-six of the electrocardiograms that were made during rest, and in thirty-five of these it occurred in the second lead. In the electrocardiograms that were made after exertion the U wave was present in eighty-six of the cases, and here again it occurred chiefly in the second lead (in seventy-eight). In only 7 per cent of the cases was the U wave never observed. The author suggests that the U wave should be watched for in pathologic electrocardiograms. He thinks that it is the manifestation of deactivation and that it probably will not appear if the cardiac muscle is weakened. Then he lists the electrocardiographic changes that are usually regarded as pathologic and shows that, if these were all considered, pathologic aspects would be present in a comparatively large percentage of persons, particularly in those of an age (18 to 22) during which a predisposition to myocardial impairment is especially low. On the basis of his observations he made the criteria for myocarditis more strict, but still he observed indications for it in 19 per cent of the cases. He concludes from this that great caution is necessary in the electrocardiographic diagnosis of "myocarditis" in persons who are free from its clinical signs. He emphasizes that as yet the electrocardiogram can be regarded only as a diagnostic aid, not as the only basis of the diagnosis.

 \*Fractures of Tubular Bones in Childhood as Seen in 726 Cases I G Smolyak —p 505  
 \*Antireticular Cytotoxic Serum in Treatment of Cancer Patients M P Fedyushin —p 534

**Fractures of Tubular Bones in Childhood**—According to Smolyak there were 726 fractures in 720 children treated in the past eleven years in the surgical division of the Filatov Hospital in Leningrad. There were 554 boys and 166 girls (33:1). A follow-up study of the late functional and roentgenologic results was made in 204 children. Among these there were seven instances of fractures of the clavicle, twenty-eight of the humerus, twenty-four of the forearm, eighty-two of the femur and sixty-three of the leg. Fractures of the clavicle gave excellent results in every instance. The late functional results after the fracture of the upper third of the humerus and diaphysis were excellent. Supracondylar and intra-articular fractures of the elbow gave the worst results as to function and to restoration of bony structure. Of fourteen cases in this group only seven presented fruitless function. It is characteristic of this fracture that the resulting deformities do not improve with time. Fractures of the forearm gave satisfactory functional results and no interference with the growth of the extremity. Of the eighty-two cases of fracture of the femur seventy-nine presented normal function and in only three was there a malunion with considerable shortening of the limb. The shortening in three cases amounted to 2 cm, in ten cases to from 1 to 1.5 cm and in sixty-five cases there was no shortening whatever. The alignment was correct in all. Of the sixty-three cases of fracture of the leg, sixty-one presented faultless function while two cases required an operation for correction of malunion. There was one instance of paralysis of the radial nerve after fracture of the humerus. The author concludes that fractures of childhood are characterized by being incomplete and subperiosteal, by the occurrence of an epiphysiolysis and a predilection for the neighborhood of the elbow. Typical Colles fracture and fracture of the ulna are rare in childhood. Epiphysiolysis was observed in 2 per cent of his material. Fractures in childhood heal twice as rapidly as they do in adults, the younger the child, the earlier is the consolidation of the fracture. Pseudarthroses are rare in childhood, the author did not observe a single instance in his series. A plaster of paris cast is applicable from the ages of 1 to 14 for all fractures except the impacted ones and those of the clavicle. The plaster of paris cast has a number of advantages over other methods. It is safe and permits of ambulatory treatment. Skeletal traction is not advisable because it has no advantage over traction of the skin or the plaster of paris cast and is associated with the danger of bone infection. Operative treatment is indicated only when there is interposition of soft tissues and in instances of old faulty union with loss of function of the extremity, in intra-articular fractures with faulty approximation of the fragments and in fractures in which there is pressure on the nerves or vessels. Massage is a valuable therapeutic measure in children above the first year of age.

**Antireticular Cytotoxic Serum for Cancer**—Fedyushin points out that the theoretical concept underlying the use of cytotoxic serum is based on the teachings of the school of A. A. Bogomolets, according to which the reticulo-endothelial system represents a definite physiologic unit the function of which is to resist the proliferative energy of the epithelium. The antireticular cytotoxic serum was prepared by immunizing a mule and later a horse by injecting them with an antigen from the spleen and bone marrow of a fresh cadaver. The titer of the serum, according to the complement-binding reaction, was not lower than 1:100. The serum is diluted in a physiologic solution in the proportion of 1:10. The serum was administered to twenty patients in whom a radical operation was performed, with the view of preventing metastases. In 102 cases the serum was used for therapeutic purposes. The stimulating dose of the cytotoxic serum was arrived at from experimental work of the school of Bogomolets and from clinical

observations of its effectiveness in infectious diseases (scarlet fever, erysipelas). Since it was felt that it would not be proper to deprive patients of proved methods of treatment, only inoperable and incurable patients were selected for treatment. A definite symptomatic improvement was noted in 40 per cent of the eighty patients who received not less than two injections. It was expressed in the improvement of the general condition, in diminution or disappearance of pain, in improvement of appetite and in disappearance of gastrointestinal disturbances. Parallel with the symptomatic improvement there was noted in all but five of the cases an increase in the cancerolytic power of the serum of the patients. All the patients felt stronger, fresher and toned up. In the majority of these cases an increase in monocytes amounting to 2 per cent was noted. The total absence of anaphylactic reactions in multiple injections of serum appears to depend on certain reactive peculiarities of a cancerous organism. A single injection of the serum does not produce a clinical effect. The effect of antireticular cytotoxic serum as differentiated from that of normal serum when used in the same doses is characterized by a definite effect on a cancerous organism. This effect is expressed in the improvement in the general condition of the patient, in symptomatic improvement and in analgesic effect. The serum appears to have a softening effect on the glandular metastases. The author's observations suggest that it is possible with the use of this serum to prolong the life of a cancerous patient. The author concludes that the antireticular cytotoxic serum increases the activity of the mesenchyma and exerts a lytic action on the parenchyma of the neoplasm. The author feels that these observations are to be regarded as the first step in the application of cytotoxins in oncology as a complementary measure to operative and radiation therapy, and as prophylaxis in patients submitted to radical operations.

**Roentgen Diagnosis of Pulmonary Embolism**—Following a brief review of the incidence, pathology and clinical symptoms of pulmonary embolism, Westermarck reviews earlier investigations on the roentgenologic aspect of pulmonary embolism and then discusses the anatomy of the pulmonary vessels. His roentgenologic studies were made in twenty-six cases in which embolism of the pulmonary artery was subsequently established at necropsy. In all these cases the roentgen examination was carried out within two weeks of the patient's death, in twelve of them a roentgenogram was made during the last two days before death. In the majority of the cases the examinations were repeated, so that it was possible to follow the development of the embolus. Ten of the twenty-six cases presented signs of pulmonary infarct, while the others were free from infarction. The author shows that the roentgenologic diagnosis of embolism of the pulmonary artery is difficult, particularly in cases without infarction. However, careful analysis of the roentgenograms taken in different directions and preferably on repeated occasions makes it generally possible to arrive at a correct diagnosis. Emboli with and without infarction present each their own typical roentgenologic aspects. In embolism of the pulmonary artery without infarction there is ischemia of the branches of the pulmonary artery on the peripheral side of the embolus. On the roentgenogram this ischemia appears as a clarified area with diminished vascular design corresponding to the extent of the embolized artery. The vascularization is maintained in the central parts of the lung. The infarct appears on suitable projection as a wedge shaped massive homogeneous shadow. In most cases, however, in which infarction is present it is possible to observe also within other parts of the lung larger or smaller wedge-shaped clarifications as in embolism without infarction.

## GOOD AND BAD RESULTS IN THE TREATMENT OF CHRONIC CERVICITIS

WILLIAM T. BLACK, MD  
MEMPHIS, TENN

Chronic cervicitis, with accompanying leukorrhea, is doubtless the most common of gynecologic complaints. Many agents have been advocated for its treatment. In current practice, however, electrosurgical treatment is recommended almost universally, having practically supplanted other surgical measures.

Celsus<sup>1</sup> was among the first to use the actual cautery in the treatment of ulcer of the cervix, and Jobert de Lamballe<sup>2</sup> is accredited with the first use of the instrument in treating chronic cervicitis. In this country, Byrne<sup>3</sup> in 1889 introduced the cautery knife as a means of removing cancer of the cervix, and Hunner<sup>4</sup> in 1906 laid the foundation for future work in electrosurgery for chronic cervicitis by his success with the Paquelin cautery. In 1921 Dickinson<sup>5</sup> called attention to the value of nasal cautery points. Hyams<sup>6</sup> in 1928 advised conization of the cervix for chronic cervicitis.

For a thorough understanding of the treatment of cervical lesions, one must be familiar with the anatomy and physiology of the cervix, as well as with the pathologic changes which take place during the course of the disease.

### ANATOMY AND PHYSIOLOGY

Although both the cervix and the uterus are developed from the müllerian ducts, the cervix differs from the uterus histologically, physiologically and pathologically. The lymphatics of the cervix communicate with those from the upper third of the vagina, extend upward through the muscular wall of the uterus, anastomose with the lymphatics from the endometrium and empty into the larger receiving channels which follow the course of the blood vessels and themselves empty into the hypogastric, sacral and iliac glands. The racemose glands of Naboth extend high into the cervix, being embedded in the fibromuscular tissue which constitutes the greater part of the cervix. The endocervix,

including the nabothian glands, is covered by a single layer of columnar epithelial cells, while the lower portion, as well as the vaginal mucosa, is covered by many layers of squamous epithelial cells.

The cervix occupies a vulnerable position, being exposed to infection from below as well as from above. The thick, tenacious, alkaline mucus from the nabothian glands aids in neutralizing the acidity of the vaginal secretion, provides a safeguard against the passage of bacteria upward, acts as a lubricant and affords a bridge over which the spermatozoa may travel into the cervical canal.

### ETIOLOGY

In the majority of cases, infection of the cervix follows laceration. Emge<sup>6</sup> stated that 80 per cent of multiparas have a lacerated cervix. Fulkerson<sup>7</sup> found diseased cervices in 33.16 per cent of 6,480 vaginal examinations, 80.1 per cent of the infections were in women who had borne children. Septic abortion is also a frequent cause.

The organisms usually grown from culture are the streptococcus and staphylococcus. Sistrunk<sup>8</sup> found various types of streptococci in 521 positive cultures. Curtis<sup>9</sup> stated that the streptococcus is the infectious agent in probably 30 per cent of cases. My observations on 103 consecutive cultures of material from the cervix were as follows:

The staphylococcus occurred in 53.4 per cent of the cases. This organism was found alone in 26.3 per cent and was associated with other organisms in 27.1 per cent. Staphylococcus aureus was present in twenty-eight cases, Staphylococcus aureus haemolyticus in four and Staphylococcus albus in twenty-three.

The streptococcus was found in 38.6 per cent of the cases, being alone in 14.4 per cent and associated with other organisms in 24.2 per cent. The nonhemolytic streptococcus was observed in ten, Streptococcus haemolyticus in seven and Streptococcus viridans in four.

The staphylococcus and the streptococcus were associated in 12.6 per cent of the cases. Staphylococcus aureus was isolated in six cases, the nonhemolytic streptococcus in six and Streptococcus haemolyticus in one.

Bacillus coli communis was present alone in 5.7 per cent and was associated with other organisms in 11.6 per cent.

The pneumococcus occurred alone in 6.7 per cent and with other organisms in 6.7 per cent.

Gram negative diplococci, morphologically resembling gonococci, were observed in one case.

Unidentified miscellaneous sporulating bacilli were observed either alone or with other bacteria in 24.2 per cent.

There was no growth in 7 per cent of the cases.

Dr. Black died Dec. 12, 1938.  
From the Department of Gynecology, University of Tennessee College of Medicine.

Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

The gonococcus is a primary factor in a large number of cases of acute endocervicitis. No doubt this organism is at times present with chronic cervicitis yet lies so deep in the tissues as to be undiscoverable in smears or cultures. Occasionally chronic cervicitis is induced by the trichomonas, this organism however, is usually confined to the vaginal mucosa.

Rosenow<sup>10</sup> has shown experimentally that the cervix may become infected through the hematogenous route. Syphilis, tuberculosis, malignant process and rarely, actinomycosis and venereal lymphogranuloma may also be sources of cervical disease.

#### PATHOLOGY

In chronic cervicitis the tissues become hyperplastic and cystic, the peglandular and perivascular structures being involved in the inflammatory reaction. An infected mucopurulent discharge with its chemically changed secretion, causes the squamous epithelial cells to become macerated, producing an erosion. At times only the basal or embryonic type of cell remains. It is from such cells that regeneration takes place after treatment. Fluhmann<sup>11</sup> has suggested that cancer may originate from these embryonic cells. Cysts are the result of deep infection and hyperplasia so excessive as to occlude the ducts by pressure. The cysts may be small and numerous or they may occur singly and

Fig. 1—A normal cervix. B cervix of normal size with chronic endocervicitis treated by light linear cauterization. C hypertrophied cervix chronic interstitial cervicitis with a few cysts treated by cauterization. D chronic cystic cervicitis treated by conization and puncture cauterization of remaining cysts. grow large enough to obstruct the external and internal os, interfere with uterine drainage and lead to extension of the infection into the body of the uterus.

#### SYMPTOMS

Leukorrhea is present in the majority of cases. If the nabothian ducts are closed, however, the discharge may be insufficient to attract the attention of the patient. When a trichomonas or mycotic infection is responsible, the discharge comes chiefly from the vagina. The purulent material frequently invades the urethra and

Fig. 2—Hypertrophied cystic cervix with large hemorrhagic cyst on anterior lip and erosion on posterior lip treated by conization followed by puncture of remaining cysts.

bladder meeting symptoms common to the two, or cystitis may develop after extension of the infection through the contiguous tissues. Infection of the pelvic glands and the sacro-uterine ligaments may give rise to dyspareunia. An uncomfortable, bearing-down sensation is a common complaint and vulvovaginitis is often present.

Although pregnancy is possible in the presence of a gross pathologic process, sterility is a sequela of chronic cervicitis in a number of cases. It is my experience that obstruction of the external os by a plug of mucus frequently is responsible for sterility in the nullipara.

I have observed that many patients referred for an abdominal operation for lateral pelvic pain, but without a palpable lesion may be relieved by the cure of a cervical infection. Backaches, menorrhagia and other symptoms may disappear after treatment of chronic cervicitis. Goodall and Power<sup>12</sup>, Sistrunk<sup>8</sup>, Moench<sup>13</sup>, Langstroth<sup>14</sup> and others have reported numerous cases in which symptoms far removed from the cervix were relieved by correction of a pathologic process in this organ. Although relief of remote symptoms by the cure of chronic cervicitis is possible, other foci should be excluded before definite conclusions are formed as to the role of such a lesion.

#### TREATMENT

Opinions differ regarding the treatment of chronic cervicitis. Topical applications are advised by some physicians, I have not, however, found them particularly effective. A cervical infection confined to the portio vaginalis and associated with vaginitis should of course be treated along physiologic lines, as sug-

gested by Roblee<sup>15</sup> and others, i. e. by keeping the vaginal flora at the normal  $pH$  of 4 or 4.2. Several authors advocate injecting the cervix with germicidal agents, for example, Ross<sup>16</sup> recommended chromic acid, Kennedy<sup>17</sup> alcohol and Moench<sup>11</sup> aniline dyes. Tovey<sup>18</sup> suggested ionization. Injections may be beneficial but will not cure an advanced infection. (I do not believe that alcohol and the dyes are being used at present.)

The surgical treatment of chronic cervicitis consists of amputation, a Sturmdorf operation or a trachelorhaphy. Although these procedures have become less popular during the past few years because of the fact that electrosurgical treatment is equally successful and more economical, surgical intervention still has a place in selected cases. The type of operation should be chosen according to the extent of the disease process and the age of the patient.

In the elderly a badly diseased cervix, especially if elongated, lacerated or prolapsed should be completely removed. Amputation may also be performed in younger women who are sterile. A case in point has recently come under my observation. A woman aged 38 had previously had a bilateral salpingectomy and on examination was found to have a deep stellate tear of the cervix, an erosion and a leukorrheal discharge. The cervix was amputated, as the condition obviously was not suitable for plastic repair or electrosurgical measures.

When the cervix is elongated and hypertrophied, a modified Schroeder or Sturmdorf operation is advisable. In the presence of an extensive laceration trachelor-

Fig. 3—Hypertrophied, cystic and lacerated cervix, treated by cauterization with electrocoagulation of laceration.

rhaphy is indicated. A laceration of 1.5 cm. or less is best treated with the cautery.

Electrosurgical operation is the method of choice for chronic cervicitis as it gives excellent results and

reduces the danger of cancer, as proved by Pemberton and Smith<sup>19</sup> and others. Carcinoma has not developed in several hundred of my cases in which electrosurgical procedures have been used. Cauterization or conization is preferable to electrocoagulation in that they are less often followed by infection. Electrocoagulation, moreover, interferes with the obtaining of a complete biopsy

Fig. 4—Slightly hypertrophied cervix showing a hemorrhagic cyst and other cysts.

specimen. Neither cauterization nor conization should be employed exclusively, however, the nature of the disease process should be the deciding factor in the selection of either of these procedures.

For a superficial endocervical lesion, lineal applications of the smallest cautery point are sufficient for mild cervicitis and the cautery should be lightly applied. Deep cauterization or conization should be avoided. For a small cervix with a persistent mucopurulent discharge, repeated light cauterization is preferable. For more advanced infections, deeper lineal burns are necessary. For the hypertrophied cystic cervix, conization, followed by destruction of cysts left by the cautery point, is the proper treatment. A laceration, if present, may be cauterized at the same time. Rarely is amputation required, even in the presence of extensive disease. In any case, one should avoid entering the uterine cavity as this adds materially to the danger of infection.

Treatment should always be carried out as soon after the menstrual period as possible. In cases of mild involvement the cautery may be applied in the office. Nervous patients and those with a hypertrophied cervix and many cysts should be sent to the hospital and treated under a general anesthetic. When there is even a suspicion of malignant change a biopsy should be made. A diagnosis of carcinoma was made by biopsy in two recent cases in which the condition was unsuspected.

#### POSTOPERATIVE CARE

The patient should be warned that the leukorrheal discharge will increase and informed of the probability of bleeding within ten to fourteen days and the possibility that the following menstrual period will be prolonged. She should also be instructed to begin taking douches after two or three days unless the uterus is retroverted and the cervix patent, in this event the douches should be postponed. Coitus should be discontinued for one month. The patient should see her physician within ten days, again two weeks later and thereafter once each month for four months or longer.

At the patient's first visit, the physician should avoid loosening the exudate for fear of hemorrhage. A germicide is gently applied to the endocervix at subsequent visits, after one month, dilation of the cervix may be necessary. The mucous membrane regenerates, epithelizes and becomes normal in appearance and function except for a deficiency of mucous secretion.

A condition worse than the original lesion may follow the indiscriminate use of the cautery and conization. The after-care also has an important bearing on the outcome. If the measures described or some similar postoperative treatment is not carried out, serious complications may arise, whether cauterization, conization or electrocoagulation has been employed. Stenosis, atresia, cellulitis, pelvic abscess and even peritonitis with death are possible sequelae of improper operative treatment or postoperative care.

Several years ago I had a case in which cellulitis followed the use of the cautery in the cervix. The operation consisted of dilation and curettage and excision of a cervical polyp, as well as cauterization. Cellulitis developed, and the patient was confined to the hospital for six weeks instead of the usual three or four days. Streptococci were observed on culture. The infection probably would not have occurred had the uterus not been entered. Though this is the only case of its type which I have had in my own surgical practice, I have observed many others, two of which are reported later.

#### REPORT OF CASES

**CASE 1**—Mrs W had a pelvic abscess after cauterization of the cervix by another physician. A posterior colpotomy was performed and the illness was prolonged for several weeks. Six months later the patient consulted me her complaints at

Fig 5—Part of the wall of a single cyst with leukocytic infiltration above and increase of connective tissue. reduced from a photomicrograph with a magnification of 200 diameters.

this time being leukorrhea, dysmenorrhea, pelvic pain, backache, a bearing down sensation, dyspareunia and nervousness. On examination the cervix was found to be eroded and pointing upward, and the uterus was retroverted and fixed. The appendages and sacro-uterine ligaments were painful to palpation. Only a laparotomy offered relief from her symptoms.

**CASE 2**—Mrs M had had a cherry electrode applied to her cervix for fifteen seconds by her husband, who was a physician. Infection developed, and a few days later a pelvic abscess appeared. I drained the abscess through the vagina. Culture revealed staphylococcus and streptococcus organisms. The patient was bedridden for eight weeks.

Fig 6—Lining of cervical epithelium below a normal cervical gland, two slightly enlarged glands and two large cysts above. reduced from a photomicrograph with a magnification of 100 diameters.

Hiller<sup>20</sup> reported two cases of cellulitis, in one of which the outcome was fatal. Goodall and Power<sup>17</sup> had a case in which streptococcal septicemia developed after a light cauterization. Masson and Parsons<sup>21</sup> described three cases of pelvic abscess following the use of the cautery. Cannell and Douglass<sup>22</sup> had a similar experience. In two cases with which I am familiar the patients died of peritonitis after cauterization.

Vivid examples of stenosis and atresia as a consequence of neglected after-treatment are presented in the following cases.

**CASE 3**—Mrs S W had a cauterization for a hypertrophied, cystic and easily bleeding cervix. On dismissal from the hospital she was instructed to consult her home physician and to return in one month for observation. She failed to do both and was not seen again until four months later. At that time she complained of dysmenorrhea. On examination the cervix appeared normal, but an opening could not be found. Under local anesthesia the cervix was incised and the canal located. The patency of the canal was established only after repeated dilations.

**CASE 4**—Mrs E had had a cauterization of the cervix by another physician three months earlier. When she visited me she was having excruciating labor-like pains in the pelvis, which she stated had persisted for one month. She had had amenorrhea since the operation. On examination the external os was found to be closed and discolored, and the uterus was enlarged. The closure of the os was punctured and a teaspoonful of dark blood was expelled.

**CASE 5**—Mrs B consulted me March 10, 1938, giving a history of having had a conization and a repair of a urethro-cystocele Nov. 30, 1937. She had not menstruated since

<sup>20</sup> Hiller Robert I. Death Following Coagulation of the Cervix. J A M A 104: 1323 (April 13) 1935.  
<sup>21</sup> Masson James C and Parsons Eloise. Cystic Cervicitis with Special Reference to Treatment by Cauterization. A Clinical Study of 1031 Cases. Am J Obst & Gynec 16: 348 (Sept.) 1928.  
<sup>22</sup> Cannell Douglas and Douglass Marion. Complications Following Cauterization of the Cervix Uteri. Am J Obst & Gynec 30: 376 (Sept.) 1935.

the operation and complained of a sense of fullness and pain in the vagina and frequent micturition. On examination the operative wound was seen to be nicely healed but a mass was discovered protruding against the anterior vaginal wall. The cervix could not be found. The patient was given a gas anesthetic, yet the cervix still could not be palpated. The mass was incised and approximately 1 quart of dark blood was evacuated. On incision of the edematous anterior vaginal wall, which extended across and obliterated the os, the cervix was located. Retained menstrual blood had pushed the recently repaired vaginal wall forward. The vaginal mucosa was sutured to the cervix, which was devoid of mucous covering. The patient's recovery was perfect.

I have found it necessary to amputate the cervixes of three patients who had had cauterizations elsewhere. Improper cervical drainage in stenosis leads to an infectious leukorrhea which results in erosion, providing a favorable soil for the development of cancer. A special dilator which I have devised has become indispensable for treatment in many cases of cervical stenosis.

These experiences are sufficient to prove that disastrous results may follow a procedure generally regarded as of minor import. If one avoids electro-surgical procedures for acute pelvic infection, does not enter the uterine cavity, restores a retroverted uterus to its normal position and carries out the proper treatment postoperatively, usually the outcome will be most gratifying. These measures moreover, will reduce to a minimum the incidence of cancer of the cervix.

#### SUMMARY

1 A specimen should be taken for biopsy from every lesion of the cervix wherein there appears to be even the slightest possibility of malignant change.

Fig 7—Cystic degeneration of cervix with large cysts in endocervix

2 A bacteriologic study showed that staphylococci and streptococci predominated.

3 Chronic cervicitis as a focus of infection should receive more thoughtful consideration. Pelvic pain, backache, menorrhagia and at times distant symptoms may be relieved by cure of an infected cervix. A gain in weight and correction of nervous instability are often noted after proper treatment of a cervical infection.

4 Penetration of the uterine cavity materially increases the danger of infection, as trauma opens an area for bacterial invasion.

5 Amputation should not be performed during the child-bearing age. A Sturmdorf operation or a modification of it is preferable.

6 Plastic surgery still has a place in the treatment of cervical lesions in selected cases. Electrosurgical measures, however, have almost superseded other methods. A trachelorrhaphy is indicated for a laceration more than 1.5 cm in length, smaller lacerations

Fig 8—Black's uterine dilator. This was made for Dr. Black a few years ago and copied by the Baptist Hospital in Memphis. On several occasions Dr. Black showed this instrument at meetings at which he gave papers on cervicitis.

are best treated with the cautery, as the result is equally good and there is less danger of subsequent malignant changes.

7 The choice between cauterization and conization should be based on the type of cervical lesion found, i.e., on whether it consists of a laceration, cystic formation or extensive hypertrophy.

8 The nulliparous cervix or the multiparous cervix without extensive disease may be treated by an electro-surgical procedure in the physician's office. In the presence of marked hypertrophy, many cysts and wide laceration, or when the patient is very nervous, the treatment should be carried out in the hospital with the help of a gas anesthetic.

9 If treatment is selected according to the nature of the lesion and the age of the patient and the necessary postoperative care is given, the outcome will, as a rule, be successful.

10 Proper care of the diseased cervix will reduce malignant changes to a minimum.

#### ABSTRACT OF DISCUSSION

DR. R. GLENN CRAIG, San Francisco: Chronic infections of the cervix have long constituted a major problem in gynecologic practice. More recently they have been recognized as a factor in sterility, pelvic pain, bladder irritability, menorrhagia and arthritis as well as in leukorrhea, and as an etiologic factor in carcinoma of the cervix. I agree with the fundamentals that Dr. Black has emphasized. However, I should like to discuss three points. 1. Surgery of the cervix is necessary in an increasingly smaller number of patients in whom equally good results can be obtained by minor procedures. When indicated, the Sturmdorf principle as illustrated by Te Linde affords excellent results. 2. Conization accomplishes its objective efficiently, namely coagulation of the cervical glands with eradication of infection. However, one cannot consider the eradication of these glands without a consideration of their physiologic importance. I believe that the destruction of these glands causes trouble and for this reason have never been able to employ the procedure without reservation. Dr. Erle Henriksen carefully followed fifty patients with this in mind and thirty-seven developed a vaginitis of varying degree. 3. Cauterization of the cervix with small electrodes has given satisfactory results. Among 100 patients two required a second cauterization and a third was operated on later incidentally to another operation. This imposes little expense with no disability and satisfactory results. Even nervous patients can tolerate this as an office procedure if they are not familiar with the details of the treatment before they

are carried out. I would emphasize the danger of intra-uterine manipulation in conjunction with cauterization. Cauterization of the cervix is one of the most valuable office procedures. When done early, the condition does not progress to the point at which surgical intervention is necessary. Infections high in the cervical canal are more difficult to treat. With the small nasal tip platinum cauteries one can coagulate quite high. However, I feel that some of these require anesthesia, dilation and cauterization under anesthesia to be treated effectively.

DR HARVEY B. MATTHEWS, Brooklyn. With reference to the bacteriology of cervical infections some ten years ago I started to do some of this work but the bacteriologist at the Long Island College of Medicine thought we were not getting anywhere because he was not sure about contamination in the enucleated cervixes or those following hysterectomy. The bacteriology that we did, showed conclusively that the streptococcus was the predominating pathogenic organism. Without an accurate diagnosis there can be no intelligent treatment. Therefore in the study of these cervical infections as in other lesions of the body, a knowledge of anatomy, physiology, bacteriology and pathology is prerequisite to proper understanding. And unless we know about the extent of the infection the nature of the infection and the pathologic condition that follows, I do not believe we shall be successful no matter what methods we use. In fact, the method is not so important as a perfected technic. The latter is more important than whether one uses the cautery, conization or what not so long as that method is efficient and the man using it has had enough experience to be classed as an expert. I have made a grouping of these cervixes which I think helps in choosing the proper method of treatment. This grouping is not original. Henry Schmidt long ago made this clinical grouping for cancer, but I think it can be used here with some degree of certainty and a great deal of help in treatment. In group 1, the lacerated cervix with superficial infection, douches are about all one needs. One can use the cautery as a "brush" by the method that Dr. Dickinson recommended years ago. Group 2 is the more deeply infected group with more or less eversion and few if any superficial cysts. Here the cautery or conization or any other method one is familiar with is all that is needed. Group 3 is the lacerated, eroded and still more deeply infected (from two to five years' duration) cervix. The upper half of group 3 can be treated successfully with a cautery or conization or any of the other methods if one knows how. The lower portion of this group has to be operated on to effect a cure. I do not believe that group 4, with the badly lacerated, everted cervix and many deep cysts, with infection of from ten to forty years duration, can be successfully treated by any method other than operation, that is, by the Sturmdorf procedure or by amputation.

DR CHANNING W. BARRETT, Chicago. There is no need to talk about cauterization or amputation or conization of an infected cervix during the acute stage. When the infection has passed or largely passed and one is dealing with a pathologic condition, the procedure should depend on the pathologic condition that is left in the cervix and so much has followed some of these procedures that I should hesitate to use them generally. Too many stenoses have followed cauterization and conization. We heard today that amputation must not be performed in a woman who is not sterile if she is a child-bearer. I cannot agree with that. I would just as soon take care of a woman in confinement after an amputation properly carried out as a woman who has never had an amputation, and usually she will deliver more quickly than a woman who is delivering for the first time.

DR LEO P. T. FITZGERALD, St. Louis. Following obstetric deliveries, I have been using the cautery on cervical tears at a period of about six weeks after the delivery. I have had the patient return to the office for examination, and with a speculum I inspect the cervix. I cauterize all small lacerations in a routine manner. In doing this I follow the area of the laceration where healing is slow. In the process of healing and contraction of the scar after cauterization, the cervix after a period of eight or ten weeks often appears very nearly normal.

DR WILLIAM T. BLACK, Memphis, Tenn. I do not agree with Dr. Barrett regarding amputation of the cervix during the child-bearing age. If electrosurgery is unwarranted a Sturm-

dorf or modification of a Schroeder operation may be performed in preference to a high amputation. If a woman becomes pregnant after an amputation, an abortion or dystocia is apt to occur. Regarding the endocervical discharge after conization, I think probably this woman had an infected endocervical condition due probably to a strictured condition. That is the reason why these cases should be followed up postoperatively for a long time. Many complications have followed the use of electro-surgery, as stated in my paper. I have heard of many complications which were never reported. I know of two deaths from peritonitis following cauterization. The point I wish to make is that women are told that electrosurgery is a very minor procedure, and this is usually true, but severe complications may ensue postoperatively.

## VISUALIZATION OF THE ADRENAL GLANDS BY AIR INJECTION

NORMAN W. ROOME, M.D.

LONDON, ONTARIO, CANADA

The method to be described for the visualization of retroperitoneal tumors is neither original nor new but is presented because I feel that it is not receiving the attention which it merits. Insufflation of a gas into the perirenal space was first used for the visualization of the soft parts of the region by subsequent roentgenograms by Carelli<sup>1</sup> in 1921. Quimby<sup>2</sup> used the method in 1923, Cahill<sup>3</sup> described his modification in 1935 and reported again on its use in 1936 and a report by Mencher<sup>4</sup> appeared in 1937. Aside from these references, however, little has appeared in the American literature.

The procedure is not one to be adopted as a routine, but in view of the current interest in tumors and hyperplasias of the adrenal glands it deserves emphasis as an important special method for the diagnosis of such lesions. Adrenal tumors have occasionally been demonstrated by other methods, such as intraperitoneal air injection (Langeron<sup>5</sup>) and intra-arterial injection of colloidal thorium dioxide (Roux-Berger, Naulleau and Condriates<sup>6</sup>), but the retroperitoneal technic has been more frequently adopted and is more generally useful. The external configuration of the kidney is well demonstrated by the air and may be of diagnostic significance especially when pyelograms are also made.

Essentially the method consists of introducing a quantity of air into the perirenal fat and filming the area several times during the following twenty-four or thirty-six hours. I have simplified the technic considerably from that described previously. The patient lies on the side opposite to that on which the injection is to be made, on a small firm pillow in the costovertebral angle. A procaine hydrochloride wheal is made in the skin at a point about 1 cm. below the twelfth rib, over the depression which occurs between the spinal and the abdominal muscles. Deeper infiltration with procaine hydrochloride, along the path of the needle, may also be made. A 3½ inch 18 gage "army type" spinal puncture needle is then inserted through the

when being directed at an angle of about 45 degrees from the vertical plane of the patient and slightly (about 30 degrees) forward of the transverse plane. The lumbodorsal fascia is recognized by the sensation of resistance and the sudden release produced when it is perforated, and the needle is introduced 2 or 3 cm beyond this point. Its point should then lie in the perineal fat inside Gerota's fascia.

The chief danger is of injecting air into the kidney from which it may rapidly enter the blood stream. The following precautions should be taken to avoid this: (1) The needle, observed for bleeding after withdrawal of its stylet; (2) is then aspirated with a syringe as a further test for bleeding and (3) the movement of the needle on deep respiration is observed for the needle moves vigorously and its distal end feels fixed when it is in the kidney whereas it moves only slightly and is relatively free when in the perineal fat. Unless air is injected no damage is done by inserting the needle into the kidney but the needle must be withdrawn and reinserted at a more vertical angle.

When the needle is in a satisfactory position, from 200 to 300 cc of air is injected with a 50 cc syringe. The air enters with very slight pressure on the plunger. When considerable pressure is necessary the position of the needle should be checked to avoid injecting the psoas muscle. I have dispensed with filtration of the

or eighteen hours, after the air has become well distributed in the fatty and areolar tissue (figs 1 and 2). It has been suggested that films be made shortly after the air injection with a period of vigorous exercise intervening. It is my opinion, however, that the series of films is likely to give more information than any

Fig 1—The roentgenogram was taken twelve hours after injection of the left side (L) and immediately after injection of the right side (R). The air is distributed about the left kidney visualizing its outline and the left adrenal while the recent injection appears as a blob about the lower pole of the right kidney.

air used and have found a valve unnecessary, as the air does not leak from the needle appreciably.

A single roentgenogram is taken immediately to check the amount and position of the air, and stereoscopic films are made six, twelve, eighteen and occasionally twenty-four or thirty-six hours after injection. The most useful films are usually those made at twelve

Fig 2—The roentgenogram was taken twenty four hours after bilateral air injection. The air has spread upward to a greater extent than in figure 1 especially on the left side where the under surface of the diaphragm is shown.

single film. Such "retroperitoneal pneumograms" have been made in fifteen cases, in eleven of which the injection was bilateral. All the films were diagnostic although it was found that a modicum of experience was necessary for the interpretation of some of them as the normal adrenal varies considerably and, because of its flatness and irregular shape, is visualized less clearly than are tumors. The patients usually complained of a feeling of fullness in the abdomen, which was not severe and which rapidly disappeared. There were no serious complications of any kind.

Most of the examinations were made in hirsute women in whom adrenal cortex virilism was suggested. No tumor was found, while enlargement of one or both adrenals was demonstrated in about half the cases. Subsequent transabdominal explorations in two cases revealed adrenal glands essentially as visualized by the air. A repetition of an injection in one case after an interval of five months showed reasonably constant visualization.

One air injection was used to demonstrate a paraganglioma in the region of the left adrenal which was responsible for paroxysmal attacks of hypertension. This tumor was removed surgically and is described in full elsewhere (fig 3). In another case the air was injected unilaterally to demonstrate the outlines of a

known hypernephroid carcinoma of the left kidney. This is done to evaluate the possible use of air injection to confirm a diagnosis of renal tumor (by the "bump" on the renal shadow) in cases in which the pyelographic appearances are inconclusive, it was thought to be definitely useful in this connection.

## SUMMARY

A simple technic for the visualization by retroperitoneal pneumograms of the adrenal glands, kidneys and other retroperitoneal soft parts was used in fifteen cases, in one of which a paraganglioma was demonstrated. More extensive use of the method is advocated for the demonstration of adrenal lesions and other retroperitoneal tumors.

## ABSTRACT OF DISCUSSION

DR. GRORCE W. FISH, New York. I first employed this valuable diagnostic procedure in 1926 using oxygen instead of air. Air was first used in our clinic in 1930. From that year until the present time approximately 200 injections have been

Fig. 3.—Visualization by air injection of retroperitoneal tumor (paraganglioma) responsible for paroxysmal tachycardia. The tumor is not completely surrounded by air but parts of its circumference are visible (arrows).

made. There have been two deaths, one in 1937 and the other in 1938 both from air embolism and both in my own cases. As far as I know, and as determined by autopsy, there was no error in technic. An inoperable pathologic process was found in the two cases. There was no evidence of direct puncture of a blood vessel, but in all probability the air injected was under sufficient pressure to break and enter a number of small diseased vessels. The symptoms of air embolism developed within five minutes after the injections. These unfortunate incidents should not condemn this procedure, but I believe that oxygen, which is rapidly absorbed, should be employed instead of air. It is the nitrogen in the air which is not rapidly absorbed. Other fatalities from air embolism following the use of air for cystograms and the determination of prostatic intrusion have been reported to me. I have no knowledge of fatalities from oxygen embolism.

DR. NORMAN W. ROOME, London, Ont., Canada. I should like only to point out that while the mortality of the procedure is admitted, the bilateral exposure of both adrenals for the purpose of determining how large they are is also a considerable procedure and carries a considerable mortality. It would seem that air injection would be preferable as a preliminary diagnostic method.

## SUBDURAL HEMATOMA IN INFANCY AND CHILDHOOD

FRANC D. INGRAHAM, M.D.

Assistant in Surgery, Harvard University Medical School and  
Neurologic Surgeon, the Children's Hospital  
AND

HENRY L. HEYL, M.D.

Research Fellow in Physiology and in Surgery, Harvard University  
Medical School and Fellow in Neurosurgery, the Children's  
Hospital  
BOSTON

Intracranial hemorrhage with the formation of a subdural hematoma is a common condition in infancy and early childhood. In the Infants' and the Children's hospitals during the past ten years we have studied and treated it in more than fifty cases. Of these, the last eleven, occurring in the year ended July 1, 1938, form the specific basis for this discussion.

There are several phases of this question which seem to us to be of general interest, and we should like to suggest a routine for the management of the majority of the patients. The condition occurs more frequently in undernourished children, and in the majority of instances there is a history of trauma. Sherwood<sup>1</sup> pointed out that subdural hematoma occurs more frequently in infants cared for in foster homes, and Peet and Kahn<sup>2</sup> refer to Rosenberg's<sup>3</sup> extensive experience with this condition, during which he had never seen it develop in a "healthy, normally developed, breast-fed child." Ingalls<sup>4</sup> has recently made a thorough study of the relationship of this condition to vitamin C deficiency. We agree that the infant with scurvy or sub-scurvy vitamin C deficiency is more prone to bleeding than the normal infant and is therefore in greater danger of having a subdural hematoma, and we realize that the illegitimate infant, or the one given poor general care, may well have a deficient diet and also be more frequently exposed to trauma than is the child living under ideal conditions, but we feel certain that these elements, although they may commonly be present, are not essential in the causation of the disease. Trauma has been a more constant feature in the history of our cases, although it has not been present in all.

It is of some interest that an apparent rise in the incidence of the disease has come during a period when the diet of the average young infant has been constantly improving, particularly as far as the administration of vitamins is concerned. The increase cannot therefore be considered due to a greater incidence of subclinical or definite scurvy. It is probable also that the general supervision of infants and young children is better now than it was a number of years ago, and this presumably means less danger of trauma.

The frequency with which subdural hematoma is found among children is more or less proportional to the

intensity with which it is sought. The fact that for the last few years we have been making the diagnosis more often is probably due to our having made a more diligent search. This effort, we feel, is well rewarded, for with adequate treatment the outlook is very promising.

The present trend in the treatment of subdural hematoma is toward conservatism. Many neurosurgeons who in the past have felt that it was important to turn down bone flaps for the removal of clots and membranes<sup>5</sup> are now advocating the much simpler method of suction and irrigation through burr holes or small decompressive openings.<sup>6</sup> It is of great interest and importance that the results of this kind of treatment are as satisfactory in the long run as the more elaborate and definitely more hazardous procedure formerly in general favor.

Because of this distinct change of attitude, it seems to us to be of particular importance to point out the marked difference in the effects of this type of disease in very young patients and in the average adult. When infants and children with subdural hematomas are seen only occasionally in a group of patients most of whom are adults, there is a natural tendency to treat all patients in the same way regardless of age. If, however, one considers the infants and young children as an entirely separate group, it becomes clear that they must be dealt with in a quite different way. We should like to emphasize the factors which make it essential that a more radical treatment be carried out with very young patients.

One must keep in mind that the brain volume is approximately doubled in the first three months of life and doubled again in the following six months. In view of this fact it does not seem unreasonable that even a thin membrane consisting of inelastic tissue should

obliterate the subarachnoid space and (2) the inflammatory reaction to the presence of blood in both the subarachnoid and the subdural spaces. Removal of bloody cerebrospinal fluid at as early a date as possible will tend to minimize this difficulty, but as long as the membrane is present absorption of fluid will be impaired and there will be a tendency to increasing hydrocephalus.

Fig. 2 (case 4)—The roentgenograms were taken after injection of air into the subdural cyst on the right through a rubber catheter inserted through the burr hole in the right temporal region. The cyst represented by the shadow was subsequently removed.

lus. With adults hydrocephalus secondary to untreated hematoma is uncommon, in infants it occurs in the majority of cases.

The question of the relative resistance of the infant brain and of the adult brain to trauma is too complex to consider in detail in this paper. It will be agreed in general that as the numerous functions of the cortex are being developed rapidly there should be as little interference with circulation as possible. To accomplish this end, membranes must be in large part removed.

#### TREATMENT

The procedure which we have adopted as a routine is planned in such a way that the radical management is safe and should be carried out with a very low mortality rate. Obviously any such plan as is here advocated must be modified to suit the circumstances. In almost every case the treatment outlined is accompanied by parenteral administration of fluids and, frequently, by repeated small transfusions.

1. Lumbar Puncture and Withdrawal of Not More Than 10 cc of Fluid. If there is evidence of marked increase in intracranial pressure, the second step should precede lumbar puncture. If the spinal fluid contains blood, daily lumbar puncture should be done until the fluid is clear.

2. Bilateral Subdural Taps Through the Coronal Suture. These taps, well away from the midline, should be done with a short needle, well sharpened but with a short bevel. Great care must be used; it is helpful to place the free thumb and index finger firmly against the scalp, the needle should be held tightly near its point so that the force used is entirely under control. As soon as the dura is penetrated the stylet should be removed, and if fluid is present it should be allowed to escape without the aid of a syringe. Normally it is impossible to remove more than a drop or two of the fluid, which is clear, colorless and has a protein content of between 15 and 35 mg per hundred cubic centimeters (negative Pandey test). If a hematoma is present there will usually be a free flow of blood-tinged yellow fluid

Fig. 1—Position of the hematoma as it occurred most frequently in this series.

do a considerable amount of damage. Obviously the danger from pressure is very great as compared with that which exists when the brain has attained its full growth.

In addition to this "constrictive" effect of the membrane, there is interference with the absorption of cerebrospinal fluid because of (1) the pressure tending to

5 Putnam, Tracy J. and Cushing, Harvey. Chronic Subdural Hematoma. *Arch. Surg.* 11: 329 (Sept.) 1925.

6 Horrax, Gilbert and Poppen, James L. The Frequency, Recognition and Treatment of Chronic Subdural Hematoma. *New England J. Med.* 216: 381-385 (March 4) 1937.

This fluid usually has a high protein content and a variable number of red blood cells. The amount of fluid removed in this way must vary according to the size of the fluid collection and the way in which the patient reacts. At the first tap it is usually desirable to remove no more than 15 cc from each side. It must be kept

treatment includes good nursing care and an adequate diet with liberal administration of vitamins. We believe it significant that all of our patients were better when operated on than when first seen.

It is of some interest that in our series there was no infection of the subdural space although in some cases as many as twenty taps were done through the scalp. The scalp was carefully shaved and cleansed and aseptic technique used. The taps were done by the house officers in their usual rotation, and the fluid cultured at least once weekly, was invariably sterile. Although pleased with the result we are inclined to wonder whether the fluid is as easily infected as is commonly supposed.

The location and the extent of the lesion have been strikingly similar in our patients. The membranous sac has in all but one case extended from the parietal region anteriorly over the frontal pole, superiorly to the longitudinal sinus and inferiorly well under the temporal lobe (figs 1 and 2).

The average convalescence from operation was remarkably rapid. Case 4 is given in detail to illustrate what we expect in this regard. Fluids wisely administered parenterally were an essential factor in the recovery. Practically all the children received at least one blood transfusion (10 cc per pound for babies), which in many instances we did not hesitate to repeat.

#### REPORT OF CASES

**CASE 1—History**—C. C., a girl aged 6 months, admitted June 21, 1937, because of sixteen generalized convulsions during the preceding month, was an illegitimate child cared for in a foster home. She was born by forceps delivery after a difficult thirty-six hour primiparous labor. Early development and diet were normal. There were no infections or history of trauma. The significant observations were listlessness, slight

Fig. 3 (case 1)—Section through a thick portion of the membrane showing various stages of fibroblastic proliferation (B, D, E) and blood vessel infiltration (A, C, F). Hematoxylin and eosin stain.  $\times 120$ .

in mind that the finding of as much as 1 cc of fluid with an elevated total protein content is pathologic and that if the needle is near the edge of the clot it may well be impossible to remove more than a very small amount. The sides are then tapped on alternate days for from one week to ten days. This gradual reduction of pressure combined with careful feeding, administration of fluids and transfusion is ordinarily accompanied by marked improvement in the patient's general condition.

**3 Bilateral Burr Holes**—These are so placed that they may later be included in a bone flap. At this time the fluid-containing cavities can be emptied completely and, if it seems desirable, may be filled with air so that roentgenograms can show the extent of the space. If a solid clot is present, it may be washed out, at least in part, at this time. Of chief importance is the determination of whether or not a definite membrane is present; if one is, the fourth step is indicated.

**4 Elevation of a Bone Flap**—Whatever solid clot may be present and as much of the membranous envelope as can be safely reached through the exposure should be removed. If a membrane is known to be present over both hemispheres, a second bone flap must be turned down after whatever interval seems suitable for the particular patient, usually one or two weeks.

We feel that by proceeding according to a regimen such as that outlined it is possible to achieve gratifying results in the treatment of this condition. Naturally the

Fig. 4 (case 1)—Region D of figure 3  $\times 900$  showing older fibroblasts rich in collagen. aniline blue stain.

rachitic beading, hemorrhages in the right retina, a palpable liver, marked bilateral spasticity, hyperactive deep tendon reflexes, bilateral ankle clonus, and Babinski responses. There was no clinical evidence of scurvy. Roentgenograms of the skull and long bones were normal. The blood and urine were normal. The Hinton reaction of the blood and the reaction to tuberculin (1:1,000) were negative. The clotting time was three minutes and the bleeding time ten minutes.

The spinal fluid was normal. Old blood was obtained from both subdural spaces when these were tapped through the coronal sutures. On July 2 burr holes were made in each temporal region and subdural hematoma membranes incised on each side. After this drainage of fluid the child improved. On July 7 an osteoplastic bone flap was turned down on the left side and the greater portion of the membrane on this side excised. An infection of the wound complicated convalescence which was otherwise uneventful. In December an osteoplastic bone flap was turned down on the right side and the membrane on this side removed. The child stood the operation poorly but was given a transfusion and improved, six hours after operation she succeeded in struggling in bed and died suddenly while attempting to get up.

**Pathology.**—The significant abnormalities noted post mortem other than those in the brain included early bilateral interstitial pneumonia, with marked pulmonary edema and moderate atelectasis; there was evidence of generalized acute and chronic infection. There was microscopic evidence of scurvy. The left side of the cerebral cortex, five months after removal of the subdural hematoma, appeared normal and the only abnormality shown by microscopic examination was moderate congestion with slight shrinkage of cells and nuclear pyknosis. There were no adhesions between the dura and arachnoid on this side, and the under surface of the dura had its usual glistening sheen. A considerable portion of hematoma remained over the right frontal pole and temporal lobe and in the middle fossa bilaterally. A fringe of hematoma averaging 2 cm in

was three minutes and the clotting time six minutes. The vitamin C content of the blood was 0.4 mg per hundred cubic centimeters, after five days of intensive vitamin C therapy it was 1.1 mg.

Lumbar puncture released grossly bloody xanthochromic fluid under increased pressure. A similar fluid was recovered from both subdural spaces by tapping through the coronal sutures. This was repeated on alternate sides daily. The child's condition improved steadily. On October 26 and November 2 burr holes were made and bilateral membranes identified. At the second operation, air was injected into the subdural space through a soft rubber catheter to help evacuate fluid. On November 12 an osteoplastic bone flap was turned down on the left side and a subdural cyst with a thick outer and thin inner wall was excised over as wide an area as could be visualized. Convalescence was uneventful, with the temperature 104 F for the first three postoperative days and normal thereafter. On November 19 an osteoplastic bone flap was turned down on the right side and a large amount of subdural fluid released but no membrane was found. Since February 1938 the patient has developed and behaved normally, with no evidence of progressive hydrocephalus.

**Pathology.**—Microscopic study of sections made through the whole membrane revealed a rather definite architecture closely resembling that observed in the preceding case.

**CASE 3—History.**—P. K., a Negro girl aged 3 months, was admitted to the Children's Hospital May 14, 1938 because of vomiting of two weeks' duration. The economic status of the

TABLE 1—Clinical Data

width was attached to the falx along the sagittal sinus on both sides. The hematoma was composed of distinct layers which could be dissected easily anatomically and identified microscopically. Around the periphery of the hematoma, for instance along the sagittal sinus, these layers merged into one membranous structure. Microscopic examination of sections taken through the thickest portion of the hematoma showed layers of fibroblasts infiltrated by layers of proliferating blood vessels. There were all degrees of connective tissue formation (figs. 3, 4 and 6), from single fibroblasts growing against a background of fading red blood cells (fig. 5) to sturdy sheets of fibroblasts rich in collagen (figs. 4 and 6). Generally speaking the younger the reaction the more peripheral was its position in the section; this stratification of fibroblasts and blood vessels seemed to give the section a rather definite architecture (fig. 3). In the center of the cross section surrounded by the most advanced fibroblastic proliferation was a cavity containing old blood.

**CASE 2—History.**—E. C., a boy aged 9 weeks was admitted Sept. 30, 1937, because of vomiting of ten days duration. The economic status of the family was fair. He had been born normally of a multiparous mother with rheumatic heart disease. He nursed poorly and was constantly fretful or lethargic. His eyes seemed to stare. The cry became increasingly piercing and the head grew large. Orange juice and cod liver oil were given in adequate amounts when he was 7 weeks old. There was no infection or postnatal trauma. The significant observations were lethargy, mild hydrocephalic facies, a head 15¾ inches in circumference, a tense anterior fontanel, bilateral internal strabismus, bilateral exophthalmos, cold extremities, symmetrically hyperactive reflexes, a subconjunctival hemorrhage on the right and normal optic fundi. Roentgenograms of the skull and long bones were normal. The blood and urine were normal. The Hinton reaction of the blood and the reaction to tuberculin (1:1,000) were negative. The bleeding time

family was fair. She was the first and smaller of twins born after a difficult ten hour labor. She was bottle fed from the time of birth and received adequate cod liver oil and orange juice after the fifth week. Twelve days before entry she had a generalized convulsion and showed residual right hemiparesis. Sulfanilamide was given for otitis media on the right. Vomiting increased during the two weeks prior to admission. The significant observations at the time of entry were temperature 103 F, pulse rate 140, respiratory rate 44, irritability, a bulging fontanel, lethargy, a piercing cry and mild bilateral otitis media. The urine was normal. Examination of the blood showed 10.5 Gm. (67 per cent) of hemoglobin, 2,920,000 red cells and 15,880 white cells per cubic millimeter, 66 per cent polymorphonuclears and 28 per cent lymphocytes. The Hinton reaction of the blood and the reaction to tuberculin (1:1,000) were negative. The vitamin C content of the blood was 9.2 mg per hundred cubic centimeters. Roentgenograms of the skull, long bones and chest were normal. Blood cultures were sterile.

Lumbar puncture yielded slightly xanthochromic fluid, it contained a normal amount of sugar (64 mg per hundred cubic centimeters) and 200 white blood cells, with 90 per cent polymorphonuclears, and 46 mg of total protein per hundred cubic centimeters. On the following day it was unchanged save for an increase in cells and total protein content. Bilateral taps of the subdural space were done through the coronal sutures. Approximately 15 cc of sterile xanthochromic fluid was released from each side in each instance the fluid contained about 1,700 cells per cubic millimeter of which one third were polymorphonuclear leukocytes and the remainder red cells. From then on the baby improved steadily. The subdural spaces were tapped on alternate days. At the end of a week she was symptom free. Bilateral burr holes on May 26 revealed thick subdural membranes on both sides, these were incised, and a free flow of xanthochromic fluid was obtained. On June 1 an

osteoplastic bone flap was turned down on the right side and a thick (one-eighth inch) gelatinous subdural membrane excised from the frontotemporoparietal region. Eight days later the left side was approached in a similar fashion and a similar membrane removed. Convalescence was uneventful and both wounds healed well. The child has remained symptom free.

Fig. 5 (case 1)—Regions B and C of figure 3  $\times 900$  showing early fibroblastic and blood vessel proliferation around extravasated red blood cells, aniline blue stain.

**Pathology**—Microscopic study of sections taken through the membrane showed essentially the same structure as that observed in cases 1 and 2.

**CASE 4—History**—J. H., a boy aged 8 months, was admitted Nov. 29, 1937, because of drowsiness and convulsions during the previous week. The economic status of the family was poor, and the child was boarded out by the working mother in a foster home. Birth and early development were normal. Cod liver oil and orange juice were given irregularly. There had been no chronic illnesses or recognized trauma. Seven days before admission the foster mother reported that the child had a convulsion. The mother found multiple ecchymotic areas over the extremities and the left side of the face. The baby became drowsy. Three days before admission internal strabismus appeared. The significant observations were drowsiness, irritability, a bulging fontanel, bilateral internal strabismus, bilateral retinal hemorrhages and a Babinski response on the left. The urine was normal. There was secondary anemia. The Hinton reaction of the blood and the reaction to tuberculin (1:1,000) were negative. The bleeding time was three and one half minutes and the clotting time five minutes. The vitamin C content of the blood was 97 mg per hundred cubic centimeters. X-ray examination showed separation of the skull suture lines but no fracture, subclinical scurvy and greenstick fractures of both bones in both forearms.

Lumbar puncture yielded clear and colorless fluid with a total protein content of 14 mg per hundred cubic centimeters and an initial pressure of 250 mm. Tap of the subdural space through the coronal sutures November 30 released 15 cc of bloody xanthochromic fluid from each side. The subdural spaces were tapped on alternate days for one week. The baby improved and became symptom free. On December 9 burr holes were made, revealing a substantial subdural membrane on the right and none on the left. On December 14 an osteoplastic bone flap was turned down on the right side and the subdural membrane removed. Since discharge two weeks later, the patient has been followed closely in the outpatient department. He is symptom free and shows no evidence of hydrocephalus. He is now 14 months old and is beginning to walk.

and say words. Psychometric studies indicate that he is about normal for his age.

**Pathology**—Microscopic study of the pathologic specimen showed a thin piece of tissue with well layered fibroblastic organization of hemorrhagic areas, there were a moderate number of monocyctic cells containing golden brown pigment.

**CASE 5—History**—B. H., a girl aged 9 months, was admitted Jan. 14, 1938, because of twitching of the right arm and leg of one hour's duration. The economic status of the family was good. The birth and early development had been normal. She had received inadequate cod liver oil and no orange juice or tomato juice, she had been bottle fed from birth. On January 12 she fell from a high chair to the floor, bruising her right cheek. She was restless that night. The next day a physician found bronchitis and otitis media, with a temperature of 104 F. Change of position of the head caused pain. She had urinary frequency, needing to void hourly. Early in the evening of admission her mother noticed twitching and weakness of the right arm and leg; the child was lethargic. The significant observations on admission were temperature 102 F, pulse rate 120, respiratory rate 30, blood pressure 130/70, drowsiness, bilateral otitis media and flaccidity and sluggish tendon reflexes on the right. The fontanels did not bulge, and there was no papilledema. X-ray examination of the skull and bones gave negative results. The urine was normal. The white blood cell count was 21,000 per cubic millimeter, the cells being predominantly polymorphonuclear. The clotting time was three minutes and the bleeding time five minutes. The vitamin C content of the blood was 0.1 mg per hundred cubic centimeters. The Hinton reaction of the blood and the reaction to tuberculin (1:1,000) were negative.

Lumbar puncture released xanthochromic fluid under increased pressure. From each subdural space about 10 cc of xanthochromic fluid was released. Subdural taps were done on alternate days thereafter. Right hemiparesis continued. On January

Fig. 6 (case 1)—Region D of figure 3  $\times 900$  showing fibroblasts (A) and collagen (B), hematoxylin and eosin stain.

27, after visualization of a subdural clot through a burr hole, an osteoplastic bone flap was turned down on the left. The underlying dura was blue over its lower two thirds; as it neared the midline it became a more normal color, and over the posterior portion of that exposed it was normal. Beneath the blue area, encased in a transparent membrane, was a thick, jelly-like purple-red clot which extended well down over the temporal lobe. This was removed completely.

After identification of a subdural membrane on the right through a burr hole, a bone flap was turned down March 1

and a thin membrane freed from the dura and removed. Neurologic examination gave negative results at the time of discharge, March 17. No weakness on the right side was demonstrable. The patient's progress has been steady, and psychometric studies show her performance to be normal.

**Pathology**—Left. Microscopic study of sections of the specimen showed a layer of only a few fibroblasts acting as a membrane around the large blood clot. Right. Microscopic study of sections of the membrane showed well established layers of fibroblasts surrounding and invading areas of red blood cell extravasation.

**CASE 6—History**—D. J., a girl aged 4 months, was admitted April 14, 1938, because of fever and convulsions of four hours' duration. The economic status of the family was fair. The birth and early development were normal. She had had adequate vitamin C and had suffered no recognized trauma. The significant observations were pallor and temperature of 104 F, spasmodic extensor movements of the fingers, a palpable liver, mild bilateral internal strabismus, normal optic fundi and a flat open anterior fontanel. X-ray examination showed the skull and long bones to be normal. Examination of the blood showed some concentration of the cell elements and 14,000 white cells per cubic millimeter, predominately polymorphonuclear.

The spinal fluid was normal. Xanthochromic fluid was obtained from each side by tapping the subdural space through the coronal sutures. The subdural spaces were tapped on alternate days, and burr holes revealed substantial bilateral mem-

brane largely removed. The child had an uneventful convalescence and was discharged from the hospital symptom free.

**Pathology**—When studied microscopically, the membrane showed recent extravasation of red blood cells and fibroblastic organization.

**CASE 8—History**—R. N., a boy aged 3 months, was admitted March 14, 1938, because of cyanotic spells and twitching on the right side for eight hours. The economic status of the family was poor. The birth and early development were normal. He was nursed at the breast for the first six weeks, after that he was given a formula with no supplement of cod liver oil or orange juice. One week before the onset of symptoms he was hit on the glabella with a bottle, without any immediate symptoms appearing. The significant observations were coma, pallor, cyanosis, bilateral internal strabismus, nystagmus, sustained right ankle clonus and a liver felt 2 cm below the costal margin. The Hinton reaction of the blood and the reaction to tuberculin (1:1,000) were negative. X-ray examination of the skull and long bones showed them to be normal. Chemical examination of the blood showed a carbon dioxide-combining power of 34 volumes per cent, the vitamin C content was 0.2 mg, the nonprotein nitrogen content 108 mg and the serum protein content 6.8 Gm per hundred cubic centimeters. Three days later the nonprotein nitrogen content was 31 mg and the vitamin C content 0.6 mg per hundred cubic centimeters.

branes. On May 2 an osteoplastic bone flap was laid back on the left side and a large thick subdural membrane excised from the frontal region. On May 20 a similar operation was done on the right side. Since discharge June 4 the patient has been seen regularly and continues to do well, with no evidence of disease of the central nervous system.

**Pathology**—The microscopic picture was essentially the same as that in the cases previously described.

**CASE 7—History**—R. G., a boy aged 2 months, was admitted Oct 10, 1937, because of convulsions during the previous three days. The economic status of the family was poor. He had been thought to be normal at birth and thereafter. Labor was of thirteen hours' duration and forceps was not used; the right parietal portion of the scalp was excoriated during delivery. There was no postnatal trauma. The child was comatose and having repeated convulsive twitching on the right side during examination. Other significant observations were a bulging fontanel, bilateral retinal hemorrhages, spastic legs and right arm, bilateral hyperactive tendon reflexes, positive Babinski responses and left ankle clonus. There was no evidence of infection or scurvy. The urine was normal. There was secondary anemia. X-ray examination of the skull showed no fracture or separation of sutures. The Hinton reaction of the blood and the reaction to tuberculin (1:1,000) were negative. The bleeding time was three and the clotting time four minutes.

Spinal fluid obtained from the lumbar subarachnoid space the day of admission was blood tinged and slightly xanthochromic. On the same day 15 cc of blood-tinged fluid was obtained from each of the subdural spaces, tapped through the coronal sutures. The child was given a transfusion and subdural taps were repeated daily, with increasing returns and steady improvement in the condition. On October 27 a burr hole was made in each temporal region, and a definite subdural membrane was seen on the right. On October 30 an osteoplastic bone flap was laid back on the right and the subdural

Spinal fluid obtained by lumbar puncture was normal. From 0.5 to 1 cc of bloody fluid was released from each subdural space by tapping through the coronal sutures. These taps were repeated daily, and the patient was given a transfusion. He improved, but the twitching persisted on the right. On March 25 bilateral burr holes were made, all revealed normal dura and cortex except the right anterior one. Here a large amount of xanthochromic fluid escaped when the dura and underlying membrane were incised. On April 1 an osteoplastic bone flap was turned down on the right as we expected, there was a large amount of fluid but no significant membrane. However, after this gross release of fluid, the child had no more twitching and improved rapidly. He was discharged April 16 symptom free save for a transient strabismus. An encephalogram made just before discharge showed a moderate symmetrical dilatation of the whole ventricular system.

**CASE 9—History**—J. V., a boy aged 13 months, was admitted May 17, 1938, because of vomiting and apathy of seven days' duration, with a right internal strabismus for the last three days. The economic status of the family was fair. The birth and early development had been normal save that the head had always been moderately large. He received adequate amounts of orange juice and cod liver oil from the age of 3 weeks. Three weeks before admission he fell from a high chair to the floor, bumping his head; he did not lose consciousness and no abnormalities were noted until the onset of his illness two weeks later. The significant observations at admission were temperature 98 F, pulse rate 104, respiratory rate 24, a moderately large head with prominent frontal bosses, right internal strabismus, and repeated projectile vomiting. The urine was normal. A blood count showed 16,000 white cells per cubic millimeter, 65 per cent of which were polymorphonuclear. X-ray examination of the skull showed the suture lines abnormally separated. The Hinton reaction of the blood and the reaction to tuberculin (1:1,000) were negative.

Lumbar puncture yielded normal fluid. Five cc of clear fluid with total protein content of 38 mg per hundred cubic centimeters was obtained from the left subdural space and 8 cc of yellow fluid with a total protein content of 185 mg from the right. Taps through the coronal sutures were repeated on alternate days, with cessation of vomiting and lessening of the baby's apathy. Bilateral burr holes were made and a large amount of fluid was released from the subdural space on both sides. No subdural membrane was seen. The child improved rapidly and now behaves in every way like a normal baby. Pneumoencephalograms made postoperatively showed mild symmetrical dilatation of the ventricular system and an increased amount of air over the cortex.

**CASE 10—History**—C. I., a boy aged 3 years, was admitted Feb. 15, 1938, because of deafness on the right side of one month's duration. The economic status of the family was good. The birth and early development had been normal; there were

Fig. 7 (case 10)—C. I. photo graphed just before discharge from the hospital.

some evidences of physical and intellectual precocity. There had been no infection or trauma until on Aug. 15, 1937, he was thrown against the windshield of a car in which he was riding when it stopped abruptly. He did not lose consciousness. The day of admission he vomited three times. The significant observations were temperature 98.6 F, pulse rate 110, respiratory rate 20, blood pressure 95/60, keen intelligence, complete deafness on the right side and partial deafness on the left side. X-ray examination showed the skull and spine to be normal. Spinal fluid obtained from the lumbar subarachnoid space was normal.

Under hospital observation for the next ten days the patient demonstrated occasional strange behavior patterns and often seemed unsteady on his feet. On March 2 burr holes were made in the parietal and suboccipital regions of the skull bilaterally. An unusually large amount of

clear fluid was released from beneath the dura over the cerebellum bilaterally, but especially over the right hemisphere. The cisterna magna was large. No subdural membrane or clot was visualized. On March 9 a pneumoencephalogram was made, which demonstrated a large space over the cerebellum and symmetrical dilatation of the lateral and third ventricles. Shortly afterward the hearing began to improve and the ataxia disappeared. On March 14 the patient was discharged in a nearly normal clinical state. This recovery has persisted and he now shows no residual effects of his injury, while his mental acuity continues to be of high caliber (fig. 7).

**CASE 11—History**—D. P., a boy aged 6½ years, was admitted June 17, 1937, because of headaches of one month's duration. The economic status of the family was fair. The birth and early development were normal. One month before entry he fell from a wagon, hitting his head on the pavement, he did not lose consciousness, but the next few days marked the onset of headaches, which increased steadily. Eleven days before entry vomiting and epistaxis started and they had recurred increasingly ever since. Significant observations were temperature 100 F, pulse rate 90, respiratory rate 25, blood pressure 100/56, irritability, a large head, early bilateral papilledema with retinal hemorrhage, unsteady gait, positive

Romberg test, symmetrically hyperactive tendon reflexes and involuntary spasms of rolling both eyes in all directions. The bleeding time was eighteen minutes and the clotting time four minutes. X-ray examination of the skull gave negative results. On July 16 burr holes revealed bilateral subdural hematomas and air injected into the subdural spaces showed them to be of great size. On July 17 an osteoplastic bone flap was elevated on the right side and the major portion of a large hematoma removed. On August 5 the procedure was repeated on the left and a hematoma removed from this side. The neurologic status is greatly improved and the original symptoms are gone. There is no evidence of permanent damage to cerebral function.

**Pathology**—Microscopic study of the pathologic specimens showed them to be composed of extravasated red blood cells, mild lymphocytic infiltration and extensive fibroblastic organization.

The clinical data presented in these eleven cases is summarized in tables 1 and 2. In each instance + stands for an abnormal and 0 for a normal condition. The operation was, of course, done only when the + sign appears under "bone flap."

#### SUMMARY

In ten cases of subdural hematoma in infants and one in an older child, we adopted radical treatment. We feel that this treatment should be carried out with a low mortality rate and very satisfactory end results.

## EPHEDRINE IN A PHYSIOLOGIC VEHICLE AND LATERAL HEAD-LOW POSTURE

IN TREATMENT OF THE NOSE AND SINUSES

SIDNEY N. PARKINSON, M.D.

OAKLAND, CALIF.

During the past decade there have been many developments relative to local treatment for infection of the upper part of the respiratory tract. There are two which I wish to discuss. One is the use of head-low posture for making the nasosinal area available for treatment. The other is the use of drugs and vehicles compatible with nasal physiology. The use of head-low posture implies recognition of the intricate and varied anatomy of the nasosinal area. The use of physiologic solutions implies realization of the function of the nasal mucous membrane. The two developments are to a great extent interdependent. Without a physiologic solution the posture would be ineffective or of limited use. Without head-low posture it is doubtful whether the need of physiologic solutions would be so easily recognized and accepted. To Dr. Arthur Proetz<sup>1</sup> more than to any other person physicians owe recognition for initiating these changes.

This situation contrasts sharply with the empiricism of the past and may be considered a new departure in rhinology. There should result a considerable change in our attitude toward the control of infection in this area. Change is inevitable as methods are correlated with anatomy and physiology. With empiricism in treatment there grew up an inordinate use of tampons, cannulas and trocars and too great a readiness to resort to minor as well as major surgical intervention during

Read before the joint meeting of the Section on Pediatrics and the Section on Radiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.  
<sup>1</sup> Proetz, Arthur W. Displacement Irrigation of Nasal Sinuses. Arch. Otolaryng. 41 (July) 1926.

acute phases of inflammation. Treatment during acute infection was attended by chemical trauma from use of unphysiologic drugs and physical trauma from instrumentation.

I am concerned with the common cold as the means by which infection becomes established in sinuses, ears and other parts of the respiratory tract. Nasal congestion during a cold interferes with venous and lymphatic

Fig 1—The lateral head low position. Ephedrine in saline solution is instilled into both nasal chambers the two sides being treated simultaneously. All the sinist ostiums of both sides are flooded by the solution. In adults this posture may be used for the displacement of iodized oil into the sinuses by the Proetz method.

circulation about the sinist ostiums. This increases the edema and congestion within the sinuses and permits accumulation of mucus which the cilia are unable to remove. This is a common complication. It often initiates a vicious cycle and is universally recognized as unfavorable to tissue defense. This cycle may be terminated if ventilation is obtained by shrinking the mucous membrane. If a sinus is able to empty itself and the circulation of lymph and blood is restored, the ability of the mucosa to rid itself of infection is increased.

The purpose of local treatment during acute infection is ventilation in order to improve drainage. Shrink-

Fig 2—The lateral head low position end view.

age of the nasal mucosa opens the meatuses and the sinist ostiums. Free ciliary drainage then takes place if in the process of ventilation the ciliary mechanism has not been damaged. This is why the selection of the drug and the vehicle is so important. An ideal drug would cause mucosal shrinkage with no evidence of

local toxicity. An ideal vehicle is one which can be in contact with the ciliated epithelium and cause no irritation. In the vehicle this implies isotonicity and a pH compatible with nasal secretion. According to present knowledge ephedrine in Locke's solution or its equivalent constitutes an efficient agent for shrinkage in a harmless physiologic vehicle.

Ephedrine acts by local vasoconstriction. As a drug it is remarkably stable. In physiologic solution of sodium chloride it may be sterilized by boiling and if not contaminated will remain apparently unchanged for months or years. This is fortunate because solutions for intranasal use should not contain antiseptics or preservatives such as are available today. A physiologic solution of ephedrine is odorless and its presence in the nose is entirely free from sensation. There is a general impression that ephedrine has a natural sting that must be disguised in some way. This is not so. Stinging, tickling or any other sensation indicates irritation from an unphysiologic vehicle. This suggests another reason why a solution for nasal use must be as nearly perfect as possible.

Fig 3—Infants and small children are best held over one's lap.

A child will usually cooperate if he is not hurt. Dr Clifford Sweet has found that with this solution his results with children compare favorably with what can be accomplished with adults. Much as ephedrine has been appreciated for its properties as a vasoconstrictor a full appreciation of its excellence cannot be had until it is used in a physiologic vehicle.

Recently other vasoconstrictor drugs such as neosynephrin hydrochloride, propadrine hydrochloride and benzedrine, have been made available. If these prove to be better than ephedrine, medical practice will be that much richer, and if they are stable in a physiologic vehicle, what has been said of ephedrine applies also to them.

I shall do no more than mention some of the drugs that traditionally have been used in the nose and sinuses during acute infection: silver proteates, volatile oils, epinephrine and cocaine and such traditional vehicles as distilled water and liquid petrolatum. Their shortcomings in local treatment have been aired widely in the literature in the past few years.<sup>2</sup> Their use is empirical and a certain amount of good may seem to be accomplished by some of them, but the closer they

2 Lierle D. M. and Moore P. M. Effects of Drugs on Ciliary Activity of Mucosa of Upper Respiratory Tract. Arch Otolaryng 10: 55 (Jan) 1934. Proetz Arthur W. Effects of Drugs on Living Nasal Cilia. Ann Otol Rhin & Laryng 43: 50 (June) 1934.

are investigated the less useful and the more unphysiologic they appear to be. Under such conditions it is no wonder that it was widely believed that a cold untreated would last two weeks whereas treated it would be over in fourteen days.

Now as to methods of applying vasoconstrictor drugs. The head-low posture advocated by Dr. Proetz is well

Fig. 4—Completion of treatment by turning the child face down permitting the nasal contents to escape from the nostrils. With this technique none of the solution at any time enters the throat.

known. The patient is supine with the head extended. The symmetry of the position makes it readily understandable. The posture which I present is that in which the head is inverted laterally. The patient lies on his side with his head bent downward exactly sidewise, using the shoulder as a fulcrum.

In treatment, preliminary shrinkage is first obtained by the use of ephedrine solution in an atomizer. This may require from five to ten minutes. The patient is

Fig. 5—Lateral nasal wall. All the nasal ostia are in the upper half. This illustration when inverted shows the important area for treatment is the lower half. The orifice of the eustachian tube is above and outside this area.

then placed in the lateral head-low posture, and solution of ephedrine is instilled into both nasal chambers. After from three to five minutes the head is rotated to face down to permit the nasal contents to escape from the nostrils.

On first acquaintance an obstacle to understanding the lateral head-low posture is its asymmetry in relation to the body as a whole, but consideration of the anatomy will reveal that it is symmetrical in its relation to the nasosinal area. In this posture all important parts of the two sides of the nose are available simultaneously for treatment. This is because the nasal chambers are narrow in proportion to their height. In treatment the upper halves of the nasal fossae are flooded and submerged. To demonstrate this I have displaced iodized oil into all the sinuses simultaneously, with the head dependent to an angle of approximately 45 degrees.<sup>3</sup> With all the variations of intranasal structure a few things can be counted on as unvarying and one of these is that all the nasal ostia are in the upper half of the nasal fossae. With the head inverted they are in the lower half and are accessible to fluid and gravity. The eustachian tubes opening on the level of the nasal floor lie outside the treated area.

My reasons for advocating head-low posture in treatment of the nose and sinuses are that it makes available all important structures within the nose and permits treatment that is entirely free from trauma.

Fig. 6—Lateral nasal wall with nasal ostia uncovered by removal of the middle turbinate. This illustration when inverted shows that fluid instilled into the nostrils when the patient is in the head low position would flood the entire nasal area.

These advantages appear to be most abundantly present in the side position, in fact, some are inherent in this and may be unattainable in any other. I would specify the following as reasons for using the lateral head-low posture:

- 1 It is practicable from infancy to old age.
- 2 It is comfortable, in fact, it resembles the position of sleep sufficiently to cause no fear in small children.
- 3 The head is at the same level as the rest of the body with the exception only of the upper part of the chest. Hence there is no flushing of the face and head with venous blood gravitating from the trunk and extremities. This is of real importance, particularly in elderly persons.
- 4 The posture is easily effected in the home or in the office and requires no special equipment. A cot and a pillow are all one needs. An intelligent mother

<sup>3</sup> Parkinson, Sidney N. A Lateral Head Low Position for Nasal and Sinus Treatment. *Arch. Otolaryng.* 17: 787 (June) 1933. Observations on Postural Treatment of Upper Respiratory Infection. *J. Pediat.* 6: 809 (June) 1935. Ephedrine in Physiologic Solution of Sodium Chloride and Lateral Head Low Posture in Treatment of the Nose and Sinuses. *Arch. Otolaryng.* 23: 344 (March) 1936.

or nurse is easily taught the technic. In the care of infants and young children the posture is best obtained over one's lap.

5 None of the therapeutic fluid need reach the pharynx or mouth in this posture or during any part of this treatment. This is important. Drugs used in the nose are for local effect only, and their general effect when swallowed or aspirated serves no useful purpose.

Those who use iodized oil for contrast radiography in the diagnosis of chronic sinusitis and other types of abnormality will find the lateral head-low position useful for displacement of the oil into the sinuses. For this I prefer unilateral rather than bilateral displacement. With the head only slightly inverted in the lateral position, iodized oil is instilled into the lower chamber. Intermittent suction is then applied. As all the sinal ostiums are submerged, all the sinuses will accept the oil if the ostiums are open. However, in the presence of much abnormality it is common for the oil to fail to enter one or more sinuses. My own use of contrast radiography is restricted to diagnosis during a latent or quiescent stage, not during a period of acute inflammation.<sup>4</sup>

1904 Franklin Street

## THE TREATMENT OF SINUSITIS IN CHILDREN

EDWARD CLAY MITCHELL, M.D.

MEMPHIS, TENN.

Sinal disease in children deserves more thoughtful consideration than it has been given. The current literature on the treatment of sinusitis is fairly comprehensive, yet no pediatric textbook has adequately pointed out the importance of this disease to the pediatrician and the general practitioner. In the hope of stimulating interest in the subject, this paper will present an outline of my experiences with sinusitis in children during twenty years. Many of the patients studied were private patients treated in collaboration with Dr. John J. Shea.

Sinusitis is observed in three stages—acute, subacute and chronic. The treatment, therefore, is not empirical but must be administered in accordance with the manifestations in the individual case. The proper selection of treatment is of course possible only through a familiarity with all those factors, anatomic, physiologic, etiologic and pathologic, which have a bearing on the development and course of the disease.

Heredity plays a definite role in the structure of the sinuses; the child tends to acquire sinuses similar to those of the ancestor whom it resembles in facial appearance. Factors which affect general growth and development, as food, vitamins, internal secretions, environment and life habits, influence the sinuses, and when this influence becomes adverse their growth is interrupted or arrested. Infections and allergy, separately or together, are chiefly responsible for sinal disease. Internal secretions may also play a part. Mortimer,<sup>1</sup> working with Cullop and others, controlled the

development of the sinuses of white rats through the action of the pituitary gland.

The role of environment in sinal infection is particularly noteworthy. I have observed fewer cases in orphanages, dispensaries and charity practice than among the well to do, even though children in more fortunate families are, on the whole, in better physical condition. This is explained by the fact that the poorer children are constantly thrown into contact with diseases of the respiratory tract and therefore gradually become immune. I have also observed that the child reared in the steam-heated home is more prone to sinal infection than the one who lives in the open. Steam heat keeps the mucous membrane congested, providing a fertile soil for bacterial growth.

It is generally known that the incidence of sinal infection is highest in the Mississippi Valley and that this incidence increases from its southern to its northern portions. The fewest cases are found at the coast. In Arizona and along the southern coast of California the infection is uncommon.

Ordinarily sinal infection occurs during January, February and March, when the sun's rays are weakest and the child's resistance is lowest. The prevalence of the infection in the fall is explained by the increased number of contagious diseases which develop at the opening of school.

The effect of tonsillectomy and adenoidectomy on sinal disease has been a subject of wide discussion. At the meeting of the Southern Medical Association in New Orleans in 1924 I<sup>2</sup> reported an analysis of 145 cases in which treatment had been given for a variety of disorders induced by sinal disease. That report contained a tabulation (table 1) of the number of patients whose tonsils and adenoids had previously been removed, including the time of their removal.

The literature of otolaryngology during the past decade has been rich in papers dealing with the action

TABLE 1—Time of Removal of Tonsils and Adenoids

of the cilia and their regeneration in the sinuses. Extensive studies have been made of innervation and of vasomotor reactions, yet a wide variance of opinion exists among sinusologists as to whether the sinuses are capable of providing immunization. One can readily understand that infection extends to the sinuses from diseased tonsils and adenoids, that perhaps temporary drainage is promoted by their removal, and again after a time infection closes off this drainage, causing the symptoms to return. But how can one explain the frequent occurrence, as shown by table 1, of sinusitis in young children, in some of whom, undoubtedly, the tonsils removed must have been healthy?

<sup>4</sup> Parkinson, Sidney N. When is Sinusitis Chronic? *Ann. Otol. Rhin. & Laryng.* 45: 721 (Sept.) 1936.  
From the Department of Pediatrics, University of Tennessee College of Medicine.

Read before the joint meeting of the Section on Pediatrics and the Section on Radiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

<sup>1</sup> Mortimer, Hector. The Hormone Factor in the Evolution, Development and Growth of the Paranasal Sinuses. *Tr. Sect. Laryng. Otol. & Rhin.* A. M. A. 1935, pp. 50-54.

<sup>2</sup> Mitchell, E. C. The Paranasal Sinus as a Focus of Infection in Children. *South. M. J.* 18: 686 (Sept.) 1925.

The frequent finding of sinal activity in children who have lost their tonsils leaves little question that removal of tonsillar tissue early in life predisposes to sinusitis. This being true, sinuses must play an intimate part in immunization from infections of the upper part of the respiratory tract. When children are enjoying good health the sinuses are peaceful, but with the onset of infection of the upper part of the respiratory tract the sinuses also become involved and the entire system is disorganized. The disease begins as rhinitis and rapidly extends into the sinuses, with or without otitis media, pharyngitis and cervical adenitis. The children

at times become seriously ill, the illness running a septic course. The affected cervical glands are deeper than those which drain the tonsils. To arrest the progress of the infection, one must promote drainage of the sinuses and support the failing immunization. Untreated, the local infection becomes general, giving rise to systemic disturbances, such as chorea, pyelitis, acute nephritis, rheumatism, carditis and, occasionally, septicemia. This fact was brought out by Mullin and Ryder,<sup>3</sup> who attracted the attention of the medical profession by demonstrating the lymphatic drainage from the sinuses to the chest, and was confirmed by Fenton and Larsell.<sup>4</sup>

In my experience this point has been amply proved. To illustrate, I cite again the paper I read before the Southern Medical Association in 1924. The conditions for which the 145 patients mentioned therein were treated as a result of sinal disease are given in table 2.

In order to gain some idea of the popular view regarding the role of the sinuses in immunization, I submitted to fifteen teachers in the field of otolaryngology the question "Do you subscribe to the theory that the sinuses play a part in immunization to infections of the upper respiratory tract?" Four of the replies were in the affirmative, seven in the negative and four noncommittal.

In this connection, Kaiser<sup>5</sup> made the statement that in his experience first attacks of sinusitis occur somewhat more commonly in children whose tonsils and adenoids have been removed.

Before beginning treatment, it is necessary to determine the type of sinusitis present and investigate the etiologic factors involved. This can be accomplished only by obtaining a careful history and making a complete rhinologic survey as well as an examination of the throat, mouth and teeth and roentgenologic and laboratory studies. The chronic sufferer may present all the symptoms which usually accompany infection of

the upper part of the respiratory tract or, on the contrary, may have no local symptoms whatever. Even though there may be no local symptoms, therefore, the examination should be thorough when the diagnosis is doubtful and a focus of infection is sought.

In addition to general physical studies, every patient with sinusitis should have an allergic survey. This should include an inquiry as to the presence of allergy in the patient's family and his own history as to contacts. The symptoms should then be considered in relation to any contacts which the patient may have had with offending allergens. Cutaneous tests are of limited value.

The distinction between infectious and allergic sinusitis usually may be made by an examination of the mucosa. In infectious sinusitis the mucosa is red and there is a thick discharge, in the allergic type the mucosa is pale and boggy and the discharge is thin and serous. The presence of eosinophils in the discharge and the finding of an increased number of eosinophils by differential blood count also indicate an allergic condition.

In table 3 are presented the chief complaints of 100 private patients observed during the past two years. The ages of these patients varied from 2 months through puberty.

None of the children under 7 years of age suffered from headache, this symptom was present principally in those at puberty. The majority of those so affected were allergic.

A comparative tabulation shows that allergy, as demonstrated by a pale membrane, was present in twenty-nine. Of that number, infection also was present in twenty-one. A family history of allergy was given in twenty-five. Tonsils and adenoids had been removed prior to sinal infection in seventy-eight. Tonsils remained in twenty-two.

Probably one of the most important phases of the treatment of sinusitis is prophylaxis. This consists chiefly of proper hygiene, a well balanced diet, cod liver

oil in sufficient amount, vitamins and sunshine, if sunshine is not available, ultraviolet rays are an excellent substitute.

Particular attention should be directed toward infections acquired in swimming pools. Sinusitis is often induced by diving and prolonged swimming.

Early cure of the common cold will go far toward preventing sinal disease. The prevention of contagion is also essential. The patient with a cold should be promptly isolated, the healthy child will withstand a moderate amount of contagion but will succumb if the contact is prolonged.

Diseased tonsils and adenoids should be removed when necessary. Normal tonsillar tissue, however, should not be disturbed.

THE TREATMENT OF ACUTE AND SUB-  
ACUTE SINUSITIS

Rest in bed is an essential feature of the treatment of acute sinusitis. The child with a high temperature should be placed in the hospital since there he is easily confined to bed, and much more can be accomplished away from the parents than is possible in the home.

Mild cathartics should be given as indicated. Salicylates for relief of pain, alkalis, particularly in the form of orange juice, and an abundance of water are necessary. Rhinorrhea should be controlled by means of codeine, belladonna and drugs of similar type. I do not recommend local treatment in the acute stage.

In extremely acute disease, when the prevailing organism appears to be *Streptococcus haemolyticus*, I have found sulfanilamide of value. This should be prescribed according to the child's weight, i.e. a daily dose of 0.2 Gm., or 3 grains, per kilogram of weight, so as to maintain a milligram concentration of 12 to 15 per hundred cubic centimeters in the blood. I have found, however, that this medication sometimes dries up the secretions rather rapidly and for this reason have not used the drug as a routine in mild or moderately severe infections.

In the subacute stage, after the discharge has become more purulent and the fever lower, although the cough may be more troublesome, nasal packs consisting of small pledgets soaked with salt solution and infra-red radiation are recommended. The infra-red lamp is used for ten minutes three times a day, being placed at a distance of 30 inches (76 cm). The discharge is removed by suction under direct inspection. In older children displacement after the modification of Proetz has been found beneficial especially if a post-nasal discharge is present. In this stage I continue to give alkalis and feed the child a substantial but fairly low carbohydrate diet. As improvement takes place, the carbohydrate intake is increased. Continued bed rest is desirable.

After the acute attack the patient should be protected from all danger of cross infection as resistance is low and infection easily recurs. A change of climate is most beneficial, particularly during the winter months. In summer the child should receive heliotherapy by direct exposure to the sun's rays, after the method of Rollier, or by simply going without clothing. Swimming, especially diving, predisposes to recurrence of the infection and should therefore be prohibited for from six months to a year following an attack.

Bryant<sup>6</sup> has recommended the use of fever therapy for acute sinus infection, on the theory that it is a natural adjunct to nature's fight against infection, helping to augment the vascular phase of inflammation. In chronic pansinusitis, however, he found that this form of treatment apparently offers no lasting benefit.

## THE TREATMENT OF CHRONIC SINUSITIS

It is my experience that chronic sinusitis in children offers a much better prognosis than that in adults. This is based on the theory, which I believe is accepted, that the sinuses, particularly the antrums, develop through pneumatization. As the air enters the sinuses, they enlarge in a manner comparable to that of a soap bubble. When the ostium is blocked, this development ceases. During the growing period there is always a possibility that the sinuses will resume their growth

when pneumatization is reestablished. I have also observed that a chronically diseased sinus in a child is an undeveloped sinus, that when development becomes normal the chronic infection no longer exists. It would seem, therefore, that the reestablishment of pneumatization is just as essential as the removal of purulent material.

I have followed a number of patients who at 8 to 10 years of age presented evidence of juvenile sinuses with constantly recurring sinusitis, as well as focal infection. When these patients had reached 15 or 16 several years after drainage, their sinuses had become normal in size and they experienced no further difficulty. I have also followed several patients who refused drainage, at maturity their sinuses remained undeveloped and not infrequently retained an infantile appearance. These persons continued to suffer from sinusitis.

Hansell<sup>7</sup> roughly classified the majority of common disorders encountered in the management of the nose and paranasal sinuses as follows:

1 Functional disturbances secondary anatomic anomalies, disturbances of the vascular mechanism secondary to environmental or external agents and those which arise secondary to some intrinsic disease elsewhere in the body.

2 Acute and chronic infection.

3 Allergic disease.

4 A combination of infection and allergy, complemented or uncomplemented by one or more of the aforementioned factors, particularly in the first and second groups.

Hansell stated that, in the diagnosis and treatment of allergy as manifested in the nose and paranasal sinuses, other diseases should not be overlooked, since the allergic symptoms may be only a part of a syndrome in which infection and secondary factors are also instrumental.

I, too, have found that, when allergic sinusitis is accompanied by infection or anatomic defects, these must be remedied before the allergy can be corrected, and, further, that an infection cannot be materially benefited so long as a coexisting allergic condition is neglected.

*Infectious Sinusitis*—In chronic sinusitis without evidence of allergy the treatment should be based on a study of the clinical picture along the following lines:

1 Are there severe local symptoms referable to the upper part of the respiratory tract, such as coughing, sneezing, running nose and headache?

2 Is there some focal infection which can be definitely attributed to the sinuses?

3 Are the sinuses developed normally according to the child's age? Are they developed equally on the two sides?

4 Is there evidence of a purulent discharge in the roentgenogram and on transillumination?

Palliative local treatment consists of application of nasal packs, suction and displacement. Irrigation of the nose with solution of sodium chloride has been used for many nasal disorders, especially those wherein the membrane is atrophied.

Medication with tincture of iodine and, in the presence of a thick discharge which induces coughing, with potassium iodide, has been effective in my experience. Tonics, vitamins, particularly vitamin C, and a properly supervised diet are essential. The administration three times a day of 5 grains of calcium lactate, one-fourth grain (0.016 Gm.) of thyroid, and  $\frac{1}{20}$  grain (0.003 Gm.) of parathyroid in milk will reduce lymphoid

7 Hansell F. K. Allergy of the Nose and Paranasal Sinuses. St. Louis: C. V. Mosby Company, 1936.

hyperplasia in children. The most successful rhythm is five days twice each month in chronic sinusitis and more frequently in acute disease.

A change of climate is most beneficial. The more chronic the infection, the longer the patient should remain in the new environment. I have found that patients who are entirely relieved in a new climate often have a recurrence of symptoms on their return to the former location.

Nickum<sup>8</sup> has been successful with short wave diathermy in the treatment of chronic sinusitis. By this method heat is produced to tolerance, increasing phagocytic action and stimulating lymphatic drainage.

For those patients who require immediate drainage for relief of secondary symptoms elsewhere in the body and for those in whom palliative treatment has failed, antrotomy and drainage for at least three or four days is deemed advisable.

#### OPERATIVE PROCEDURE OF SHEA<sup>9</sup>

If the child's condition warrants, ether is the best anesthetic since by its use the operation may be carried out deliberately and thoroughly. In the presence of renal infection either nitrous oxide or an ethylene mixture is safer than ether, although the operation must be performed rapidly. Use of avertin with amylene hydrate supplemented by the local application of 4 per cent solution of cocaine minimizes the risk of postoperative pneumonia.

The nares are cleansed by suction and the site of the operation is pruned with a 30 per cent solution of alcohol. The ostium of the antrum is sought and dilated; if the ostium is not found, the membranous tissue of the middle meatus is perforated. If the operation is to be a success, the patency of the ostium must be maintained. The material is obtained through a syringe and needle. If the patient is suspected of being allergic, sterile physiologic solution of sodium chloride is instilled and withdrawn; otherwise, brain broth medium is used.

In younger children the naso-antral window is made with an antral trocar, whereas in older children a curved gouge is employed. The aperture is shaped to fit the rubber tube by a series of dilations with Ritter sounds. The catheter is next inserted, one of the smaller Ritter sounds being used as an obturator; one can easily tell when the catheter slips through the window. Suction is then applied to the drain, by means of a medicine dropper, through which the contents of the antrum are visualized. The presence of air bubbles in the antral contents should be noted, as these bubbles indicate the patency of the secondary opening. If no bubbles are visible, saline solution is forced through the tube until it appears in the back of the nose or the nasopharynx, thus forcing out any mucous obstruction to the ostium. Suction is again attempted and if bubbles are still not visible through the glass, the tube is removed and the operation repeated, special attention being given to the ostium.

#### USE OF VACCINES

Krise<sup>10</sup> and Foster<sup>11</sup> reported the experimental production of colds with bacteria-free filtrates. Dochez and his co-workers<sup>12</sup> have demonstrated the susceptibility of chimpanzees to colds simulating those in human beings when inoculated intranasally with bacteria-free filtrates obtained from the nasal washings of human beings with common colds. In 40 per cent of the

animals a typical common cold developed. When these experiments were performed on human beings, colds were produced, though generally of a mild degree. The results of Dochez and his co-workers indicate the complex nature of the infections of the upper part of the respiratory tract and the possible part played by filtrable viruses and visible bacteria.

For many years vaccine has been employed to increase resistance to these infections, nevertheless the therapeutic effect leaves much to be desired. Vaccinated and nonvaccinated groups of persons have been compared as to their susceptibility to infection, and it has been found that the majority of mixed vaccines confer only slight protection against infection of the upper part of the respiratory tract.

It is my custom to use autogenous vaccine during the winter following the antrostomy. Culture material is obtained from the sinuses by suction. This material usually is mixed with a seasonal vaccine made from an active culture of those organisms which seem to be prevalent during the season. The vaccine is given at the first appearance of cold weather, which in Tennessee is generally in the latter part of October, and is repeated during the latter part of December and again in March.

TABLE 4—Treatment Carried Out by Mitchell and Shea

	Cases
Antrostomy	71
More than one antrostomy	6
Removal of tonsils at time of antrostomy	21
Removal of remaining tonsillar tissue	12
Sulfanilamide medication	18
Blood transfusion for secondary anemia	6
Giving of autogenous vaccine	20
Administration of stock vaccine	A few cases

Five small doses are administered in each treatment, at four day intervals. Although I have not found that this prevents colds, I believe it has reduced their severity.

From these studies it appears that the primary infectious agents are filtrable viruses and that ordinary pathogenic bacteria become activated and play a secondary but important part.

#### ALLERGIC SINUSITIS

Allergic sinusitis may be induced by any or all of three different types of allergens: (1) pollens, (2) inhalants other than pollens and (3) food.

The elimination of only one type of allergen is often insufficient, as in the home articles of furniture, such as covers of sofas may contain horsehair or dust to which the patient is sensitive. Every irritant must be excluded before relief can be obtained. If the irritants are inhalants other than pollens, contact with these articles should be avoided.

Immunization to pollens may be acquired by two methods: (1) a complete change of environment to a locality in which the offending pollens do not exist, and (2) the use of pollen extracts. A change of environment often enables the patient's resistance to the allergen to develop so that he may return to his habitual locality without suffering a return of symptoms.

Allergy is so prevalent and so frequently a cause of sinusitis that the practitioner should have at least a working knowledge of this subject. In many cases it is overlooked because the importance of this phase of sinusitis is not appreciated. A large number of my failures to benefit sinusitis, particularly before allergy was well understood, were due to the fact that the

patients had infection in addition to allergy, and sometimes allergy alone, which was at that time thought to be infection

Table 4 summarizes the treatment carried out by Dr Shea and me jointly in 100 cases of sinusitis observed within the past two years

I shall report several cases, observed for approximately twenty years, which illustrate the effect of treatment on the health and development of the sinuses

#### REPORT OF CASES

CASE 1—E S, a child aged 11 years was brought for examination because of generalized rheumatism. Physical examination revealed infected tonsillar tags and hypertrophied adenoids. Urinalysis indicated the presence of pyelitis. A roentgenogram showed poorly developed frontal sinuses and dark cloudiness of the antrums and ethmoids. The diagnosis was pansinusitis, secondary arthritis and pyelitis.

The adenoids and reformed tonsillar tissue were removed and the sinuses were drained. A roentgenogram made three years later showed the antrums and ethmoids clear and development of the frontal sinuses increased. At the last report four years thereafter, the patient was free from symptoms. We were unable to make a further roentgenographic study at that time.

CASE 2—J McD, a boy aged 4 years, complained of pain in the region of the right maxillary sinus and a mild headache. Two weeks prior to examination he had had a septic temperature ranging from 100 to 104 F. The ethmoids and both antrums were cloudy and the tonsils were inflamed and enlarged. Studies of the urine revealed acute pyelitis.

The tonsils were removed and the sinuses drained. *Staphylococcus aureus* was found on culture. Subsequent roentgenograms at intervals demonstrated a continued improvement in the growth of the sinuses. At the last examination, made eight years after operation, they were entirely normal and the patient was without symptoms.

CASE 3—B C, a boy aged 5 years had suffered from frequent colds since early infancy. The tonsils and adenoids had been removed one year earlier. Temporary improvement thereafter was followed by a return of symptoms. The child was brought for examination because of a cold, loss of weight and recurrent bronchitis with fever. Heavy shadows were observed over both antrums, and the ethmoids were cloudy. Since the season was late spring, it was thought best to prescribe only medical treatment through the summer. He improved to some extent during this time but with the beginning of fall his trouble returned. Examination showed the shadow over the antrums and in the ethmoids to have increased in density. The sinuses were then drained and both *staphylococci* and *streptococci* were obtained on culture.

A roentgenogram made one month after operation showed no change in the shadow. Another, a year later, revealed some improvement. Soon thereafter the child was taken to Switzerland, where he lived in comparatively good health for several years. On his return to Memphis the colds recurred and a streptococcal infection, mastoiditis and secondary meningitis developed, with a fatal termination. The sinuses were never fully developed. It is now believed that an allergic condition was responsible for failure of the treatment.

CASE 4—C L, a boy aged 8 years, had suffered from bronchial asthma since the age of 15 months. A history of allergy in other members of the family was obtained. The child had been placed on a dietary regimen which not only failed to alleviate the asthma but led to a loss of weight. His tonsils and adenoids were removed at the age of 3 years. Several subsequent changes in climate and in diet were ineffectual in relieving the asthma.

On examination the patient presented the typical symptoms and signs of sinusitis. In the roentgenogram a shadow was seen over both antrums, although the floor of the antrums could be clearly distinguished. The diagnosis was ethmoiditis with slight involvement of the antrums.

Medical treatment, including suction, was advised. A culture of the discharge revealed both *streptococci* and *Staphylococcus aureus*. An autogenous vaccine was administered and the

attacks became less frequent thereafter, although the patient continued to suffer on exposure to certain allergens. Roentgenograms repeated at intervals of two years have demonstrated an increasing development of the sinuses.

In this case the sinusitis was both infectious and allergic.

CASE 5—B B, a boy aged 9 years, had been subject to frequent colds since early infancy. His tonsils and adenoids had been removed at the age of 4 years. After influenza and bronchitis three years previously the child had had numerous attacks of bronchitis. He had also been troubled with severe spells of coughing on lying down at night and with considerable sneezing on arising.

The roentgenogram revealed cloudiness of the ethmoids and a shadow over both antrums. The diagnosis was double empyema of the antrums with ethmoiditis.

As summer was beginning and the child was in poor physical condition, it was decided to postpone surgical treatment until fall. Meanwhile he was taken to the Massachusetts coast, where his symptoms subsided. In September he had an acute attack of bronchitis of the asthmatic type. A subsequent examination disclosed an increased density in the antral shadows.

Drainage was instituted, and *Staphylococcus aureus* was seen on culture. An autogenous vaccine was given, and medical treatment was continued at intervals for one year. Since that time he has had no further symptoms. Roentgenograms made every two years have shown a progressive growth of the sinuses, at the last examination they were found to be normally developed.

CASE 6—S S, a boy aged 8 years, was admitted to the hospital for loss of appetite, loss of weight and a ready tendency to fatigue. He had had malaria six months earlier. The child was nervous and underweight, his tonsils were enlarged, his adenoids hypertrophied and several teeth decayed.

After removal of his tonsils and adenoids the patient began to exhibit general improvement. A few months later he had an acute illness resembling influenza. After the acute symptoms subsided a roentgenogram was made, which demonstrated double empyema of the antrums with ethmoiditis. The sinuses were poorly developed.

Drainage was instituted and subsequently injections of autogenous vaccine were given. Three roentgenograms, made during the next few years, revealed continued growth of the sinuses. The patient's general health has also improved and he is now practically free from symptoms.

CASE 7—F P, a girl aged 11 years, was admitted to the hospital because of vomiting, fever, marked general edema of the face and extremities and impaired vision. The child's adenoids and tonsils had been removed at the age of 5 years. Since that time she had remained well except for an occasional cold accompanied by severe frontal headache.

Physical examination revealed swelling of the feet and legs and puffiness under the eyes. The heart was irregular, although there was no murmur. The nasopharynx was inflamed and swollen and there was a purulent postnasal discharge. The urine contained an enormous number of pus cells, numerous casts and blood cells and 3 plus albumin, the quantity of the urine was diminished. A chemical analysis of the blood showed 12 mg of creatinine per hundred cubic centimeters and 31.5 mg of urea nitrogen. In the roentgenograms a heavy shadow was seen over the ethmoids and both antrums. The heart was enlarged in all measurements. Examination of the eyegrounds gave negative results, the ophthalmologist reported that the impaired vision was temporary, being induced by either bulbar neuritis or uremia. The diagnosis was acute parenchymatous nephritis following empyema of the antrums.

Twenty-four hours after the patient's admission the generalized edema had increased and she was unable to retain anything except a small quantity of water. Since the child was so rapidly losing ground, antrotomy with drainage was performed on the second day. A pure culture of *Staphylococcus aureus* was isolated.

The headache ceased within twenty-four hours after operation. Recovery was slow, however, the albumin persisted in the urine for one month. Subsequent analyses showed evidence of mild infection at times. A roentgenogram made two years after operation revealed only a faint antral shadow. At the

it important? The hydrogen ion concentration of blood is about 74, of nasal secretion it varies perhaps from 65 to 85. It differs with individuals and it varies during colds and allergic attacks. In using the solution it has been found that if the  $p_{\text{H}}$  is low, that is if it is around 60, 65 or even 70, it causes stinging or burning in the nose. A child won't tolerate it. It seems best to keep the  $p_{\text{H}}$  above 74, and it is probably well to have it as high as 84. When the solution is introduced into the nose the absorption of carbon dioxide from the respired air brings the  $p_{\text{H}}$  down within a few seconds. In this locality we find it best to use tap water instead of a buffered solution of distilled water. It is much more stable. In Oakland the  $p_{\text{H}}$  of tap water runs about 8.5 and it stays there. When the water is boiled the  $p_{\text{H}}$  goes higher but on cooling it comes down again. We use tap water plus sodium chloride plus ephedrine. The solution is boiled and kept in sterile screw capped bottles. It is isotonic, it has a correct  $p_{\text{H}}$  for nasal use and it is stable. The purpose is to prevent interaction between the solution and the fluid content of the epithelial cells. Does the  $p_{\text{H}}$  change on standing? Not if tap water is used. If distilled water is used, as in Locke's and Ringer's solutions, the  $p_{\text{H}}$  tends to drop too low. How long does one keep the solution? If it is correctly made it will keep for many months.

## CHRONIC SUPERFICIAL GASTRITIS

### CORRELATION OF GASTRIC ANALYSIS AND CLINICAL STUDY WITH GASTROSCOPIC EXAMINATION

JOSEPH BANK, M.D.

PHOENIX, ARIZ.

AND

JOHN F. RENSHAW, M.D.

CLEVELAND

The study of gastritis has received an added impetus with the introduction of the flexible gastroscope of Schindler. Doubt exists in the minds of many physicians as to what constitutes gastritis pathologically. Likewise the criteria for the gastroscopic diagnosis of this condition have been questioned. While clinical diagnosis of gastritis is possible, it is admittedly uncertain. It seems to us that the study of patients with a gastroscopic diagnosis of gastritis offers a logical basis of departure for the investigation of this condition. Like Benedict,<sup>1</sup> Borland,<sup>2</sup> Carey,<sup>3</sup> Schloss<sup>4</sup> and others, we have accepted for purposes of discussion Schindler and Ortmayer's<sup>5</sup> classification of chronic gastritis into the superficial, hypertrophic and atrophic types. The adoption of a uniform nomenclature should aid in the standardization of diagnostic criteria.

The purpose of this investigation is to study the gastric function as judged by fractional gastric analysis and to record other clinical observations in patients for whom a gastroscopic diagnosis of chronic superficial gastritis has been made. We have limited this discussion to chronic superficial gastritis because we believe it advantageous to consider each type of gastritis independently.

This study comprises a group of fifty patients with symptoms in the upper part of the abdomen in whom

no abdominal disease other than gastritis was established. Those with organic gastrointestinal disease or advanced systemic disease were excluded. Each patient's complete history was taken and physical examination, roentgen study of the stomach, colon and gall bladder, examinations of the stool, sigmoidoscopic study, analysis of blood and urine, the Wassermann test, fractional gastric analysis and bile drainages were done. Most of the patients were ambulant and were examined in the office.

The gastroscopic study was performed in the manner advocated by Schindler. The Schindler-Wolf flexible gastroscope was introduced into the fasting stomach after preparatory anesthesia of the pharynx with pontocaine hydrochloride and aspiration of the contents. The gastroscopic diagnosis of chronic superficial gastritis was based on the observation in varying degrees of reddening of the mucosa with patches of adherent greenish gray to white exudate, edema evidenced by a swollen, moist, boggy appearance, diffuse or punctate superficial hemorrhages, erosions, and evidence of friability of the mucosa.

For studying disturbances of gastric secretion and motility the ordinary two hour fractional gastric analysis was performed in each case. After aspiration of the gastric contents during fasting a test meal of approximately 35 Gm of bread and 350 cc of water was given. Extractions were made every fifteen minutes. At the end of the two hour period the stomach was emptied and the contents were measured. Each extraction was titrated for free and total acid and tested for occult blood with benzidine. All the examinations were done under our supervision.

### GASTRIC CONTENTS DURING FASTING

Fasting secretion was considered normal when the free hydrochloric acid was between 10 and 19 and the total acidity between 20 and 34 points. Fasting motility was considered delayed if the gastric contents exceeded 50 cc. In this series free hydrochloric acid was absent in twenty-seven cases (54 per cent), normal in three (6 per cent) and above normal in twenty (40 per cent). Delayed motility of the fasting stomach was infrequent, being noted in only four cases (8 per cent).

### POSTPRANDIAL ACIDITY

Little attention has been paid to the secretion and the gastric motility as judged by fractional gastric analysis in chronic superficial gastritis diagnosed with the gastroscope, although mention is made of secretory data in all cases of gastritis grouped together. Swalm, Jackson and Morrison,<sup>6</sup> in describing forty-eight cases of various types of gastritis, including nine cases of peptic ulcer, pointed out that there was no definite relation between gastritis and gastric secretion but made no mention of the motility. Schindler<sup>7</sup> stated that there is no characteristic acidity in chronic superficial gastritis. Henning<sup>8</sup> expressed the belief that chronic gastritis is characterized by a tendency toward decreased acidity. In various types of gastritis he found achylia in 15 per cent, anacidity in 21 per cent, hypo-acidity in 32 per cent, normal acidity in 21 per cent and hyperacidity in 11 per cent. Larrimore<sup>9</sup> stated that "although a deficiency

<sup>9</sup> Larrimore, J. W. The Significance of Chronic Gastritis. *Am. J. Digest Dis. & Nutrition* 3: 215-219 (June) 1936.

in gastric juice is the most important functional finding, it is by no means pathognomonic. The inference of gastritis from the mere finding of an achlorhydria or an achylia is untenable." Bloomfield and Pollard<sup>10</sup> concluded that gastritis is not a specific lesion of anacidity. Faber<sup>11</sup> said that chronic achylia has an exogenous cause and is produced by external factors acting in the stomach.

The postprandial acidity in our cases was divided into four groups (table 1). Hyperacidity was observed in twenty-five cases (50 per cent). In ten cases (20 per cent) acidity was within normal limits. Subnormal acidity was seen in two cases. Achlorhydria was encountered in thirteen cases (26 per cent), in six of which there was achylia.

Although opinions on the relation of gastritis to secretion differ, it seems significant to us that only 20 per cent of our patients had normal acidity and 50 per cent had hyperacidity. This is contrary to the observations recorded by other authors when they studied all types of gastritis as a group. Can it be that superficial gastritis precedes the development of other forms and that in this superficial or catarrhal stage the acid-secreting elements are stimulated, only to be depressed later by the more advanced forms of gastritis, namely the atrophic or the hypertrophic forms? Whether it is true that the more advanced types increase the frequency of anacidity cannot be surmised from data available in the literature at the present time. Thomsen<sup>12</sup> found that in gastritis produced experimentally with various agents hypersecretion occurred from some and achlorhydria or achylia from others.

The incidence of achlorhydria in our series was less than that reported by Henning<sup>8</sup> for all types of gastritis. However the occurrence of achlorhydria in 26 per cent of our patients with chronic superficial gastritis cannot be unrelated. Vanzant<sup>13</sup> found achlorhydria in 12 per cent of patients without gastrointestinal complaints. Bockus, Bank and Willard<sup>14</sup> noted achlor-

or less than normal amount of secretion during fasting and the fact that in most cases less than half of the two hour extraction was fluid.

MOTILITY

Bell and McAdam<sup>15</sup> have shown that the rate of emptying of a test meal by the stomach was remarkably constant in normal persons. Their observations were checked by roentgenologic examination. Bockus, Glassmire and Bank<sup>16</sup> in a study of 200 cases of duodenal ulcer concluded that fractional gastric analysis carried out in the same manner as in this study is a

TABLE 2—Gastric Motility by Fractional Gastric Analysis in Fifty Cases of Chronic Superficial Gastritis

Type of Motility	Range of Residue at Two Hours	Number of Cases	Percentage
Delay grade 1	50 to 99 cc gastric contents and 20 to 49 cc food	20	40
Delay grade 2	100 cc or more gastric contents and 50 cc or more food	8	16
Normal	Less than 50 cc gastric contents and 20 cc food	21	42
Rapid emptying	Empty in less than two hours	1	2

more delicate measure of gastric motor impairment than the ordinary six hour roentgenologic observation.

For purposes of discussion the delay in motility was divided into two simple groups (table 2). When from 50 to 99 cc of gastric contents with 20 to 49 cc of food remained at the end of two hours, delay was classified as of grade 1. The presence of both 100 cc or more of gastric contents and 50 cc or more of food placed the delay in grade 2.

By these standards a total of twenty-eight patients (56 per cent) showed delayed emptying. Of these, the delay in twenty cases was classed as grade 1 and in eight cases as grade 2. The secretion in the cases of delayed emptying was hyperacid in nineteen, normal in five, hypo-acid in one and achlorhydric in three. Hypermotility was present in only one case (one of achlorhydria), in which emptying occurred in ninety minutes. The presence of delayed motility in 56 per cent of these cases was all the more significant because of the incidence of achlorhydria in 26 per cent of the series (13 cases). Three patients with achlorhydria showed definite delay. Nine of them showed normal emptying. Rapid motility with achlorhydria is a well known clinical observation. The absence of rapid emptying in patients with achlorhydria and gastritis is significant because the gastritis seems to delay the motility. In a series of 210 cases of achlorhydria, Bockus, Bank and Willard<sup>14</sup> found rapid emptying in 41.4 per cent. They also noted that rapid emptying was less frequent in cases of achlorhydria in which gastritis was presumed to exist.

No attempt was made by us to estimate the extent or severity of the gastritis and to correlate it with the secretion and motility. However, in all the cases the gastritis was diffuse and apparently limited to the body of the stomach.

RELATION OF RETENTION (BY ROENTGEN STUDY) TO GASTRITIS

While we are not attempting to discuss the relation of gastritis to ulcer, sixty-five patients with ulcer were studied with the gastroscope for the purpose of estimat-

TABLE 1—Postprandial Acidity in Fifty Cases of Chronic Superficial Gastritis

Secretion	Range Free Hydrochloric Acid	Total Acid	Number Cases	Percentage
Hyperacid	Over 40	60	25	50
Normal	36 to 49	40 to 59	10	20
Hypo-acid	Under 35	41	2	4
Achlorhydric			13	26

hydria in 6 per cent of patients with gastrointestinal symptoms. It is apparent that the incidence of anacidity in chronic superficial gastritis is higher than in the patients who had been examined by the aforementioned authors.

The relation of delayed motility to acidity may be observed from the fact that the delayed motility was greater in the group with hyperacidity (66 per cent) than in the group with hypo-acidity (33 per cent). That the secretion per se is not the dominant factor in the delay is indicated by the occurrence of a normal

ing the frequency of gastritis in patients with gastric retention demonstrated radiographically. This group consisted of thirty-three patients with duodenal ulcer, thirty with gastric ulcer and two with both gastric and duodenal ulcers. Of these sixty-five patients, six hour retention of varying degrees was manifested by sixteen (24.6 per cent) and gastritis by twenty-six (40 per cent). The incidence of gastritis was not found to depend on the frequency of gastric retention.

The incidence of gastritis was practically the same in the retention (44 per cent of total retention) and the nonretention (38 per cent of total nonretention) groups. Henning<sup>17</sup> and Schindler<sup>18</sup> stated that chronic gastritis is present in approximately 40 per cent of all patients studied with the gastroscope. In the group of patients with ulcer the occurrence of gastritis with retention was not higher than the general incidence of gastritis. Therefore the gastritis cannot be considered the result of the retention.

#### SYMPTOMS

Eusterman<sup>15</sup> called attention to the lack of close correlation between symptoms and the presence of inflammation of the gastric mucosa. Konjetzny<sup>19</sup>

TABLE 3—Duration of Symptoms of Gastritis

Years	Less than One	1-2	2-5	5-10	10-15	15-20	20-30
Number of cases	4	4	11	11	1	4	4

TABLE 4—Incidence of Gastritis According to Age

Age (Years)	Less than 20	20-29	30-39	40-49	50-59	60-69	70-79
Number of cases	1	8	14	11	9	1	2

expressed the belief that gastroduodenitis may produce a syndrome of ulcer without the existence of ulcer. Schindler, Ortmyer and Renshaw<sup>20</sup> found a syndrome of duodenal ulcer in about one third of their selected cases of gastritis and called attention to the presence of periodic or constant distress in cases of superficial gastritis. Faber<sup>11</sup> pointed out that symptoms of ulcer are not necessarily pathognomonic of ulcer but may be due to gastritis.

In four patients of our series, symptoms in the upper part of the abdomen were not present. Thirteen patients (26 per cent) presented symptoms characteristic of duodenal ulcer. The pain was in the epigastrium and was relieved by food and alkali. Pain during the night was frequent in this group. The gastric secretion varied. It was hyperacid in seven cases, normal in two, achlorhydric in one and achylous in one. The gastric motility by fractional analysis was normal in three and delayed in ten.

Intolerance of food and postprandial distress soon after meals were present in thirty-five cases. Pain was noted in thirty-seven and was located in the epigastrium, substernal region and upper right quadrant of the abdomen. The pain was described as gnawing, pressing

or cramplike. A burning sensation was present in nine instances. Vomiting occurred in eight, including one of hematemesis which could not be explained on any basis other than the gastritis.

The occurrence of diarrhea with achlorhydria has been termed "gastrogenous diarrhea," implying gastric origin. The exact cause of the diarrhea is as yet unknown, but the often accepted idea is that it results from absence of acid in the stomach, since it is relieved by the administration of hydrochloric acid. Bockus, Bank and Willard<sup>14</sup> reported the occurrence of diarrhea in twenty-one of 210 cases of achlorhydria. Only two patients had achylia. In addition, they observed fifteen cases of pernicious anemia, in only one of which diarrhea was present. It may therefore be assumed that the degree of reduction of acidity per se was not the underlying factor. It is possible that an accompanying inflammatory process was responsible for the diarrhea. Henning<sup>17</sup> in reviewing 700 cases of gastritis diagnosed with the gastroscope, found diarrhea in 10 per cent.

In our series diarrhea occurred in eight cases (16 per cent). In four of these there was hyperacidity and in four achlorhydria (in one associated with achylia). It is interesting to note that only four of the thirteen patients with an acidity complained of diarrhea. While it is true that the ultimate cause of this type of diarrhea is not definitely proved, the assumption may be made that the gastritis, and perhaps a concomitant intestinal abnormality, may be responsible. In this respect we are in accord with the expressed opinion of Gutzeit<sup>1</sup> that inflammation of the small intestine may be associated with superficial gastritis and produce diarrhea. Bockus, Bank and Willard<sup>14</sup> noted the occurrence of duodenitis, as determined by culture of material from the duodenum in 82 per cent of cases of achlorhydria with gastritis and in 58 per cent of the entire series of cases of achlorhydria, suggesting that gastritis is a factor of importance in the development of duodenitis in cases of achlorhydria.

#### OBJECTIVE OBSERVATIONS

Loss of weight occurred in twenty-three of the fifty cases. The actual loss was recorded in fifteen of these and varied from 6 to 27 pounds (2.7 to 11.8 Kg). The average loss was 17 pounds (7.7 Kg). A mild degree of anemia existed in 8 per cent of the cases. A plus 4 benzidine reaction of the stool was obtained in 42 per cent.

The frequency of foci of infection was outstanding. Teeth were recorded as foci of infection only when multiple apical abscesses were found after extraction. Pyorrhea was recorded when half or all of the teeth had been removed for pyorrhea. In the majority of cases in which tonsils were recorded as diseased, they had been removed since the onset of gastrointestinal symptoms and been found infected. The patients with sinusitis had been treated for years, and many had had to seek a change of climate after other treatment had failed.

Forty-three patients (86 per cent) had definite foci of infection. Of these twenty-seven (54 per cent) had multiple foci. Foci of infection occurred as follows: infected teeth in twenty, pyorrhea twelve, diseased tonsils twenty-four, sinusitis seven, chronic bronchitis two and giardiasis one. It may be significant that nineteen of the patients were edentulous as a result of pyorrhea or infected teeth and had upper and lower

21. Gutzeit, K. cited by Schindler and Ortmyer.

dental plates Faulty mastication has been mentioned by some writers as a possible contributing cause of gastritis

The use of alcohol and tobacco is often stated to be a common cause of gastritis The majority of our patients did not drink or smoke In the other cases neither of these agents was used in sufficient degree to be considered an important etiologic factor

#### DURATION OF SYMPTOMS

The prolonged duration of symptoms was a prominent feature in this group The period during which symptoms were present ranged from less than one year to thirty years Four patients complained of symptoms for less than a year Four others had had symptoms from one to two years The remainder had had symptoms from three to thirty years (table 3)

#### AGE AND SEX

The age of patients in this series varied from 19 to 79 years (table 4) Twenty-two were men and twenty-eight women The frequency was greatest in the fourth decade (fourteen cases) Only one patient was under 20 Fifty per cent of patients were between 30 and 49 Chronic superficial gastritis appears to begin in the third and fourth decades and has a prolonged course

#### SUMMARY

A study was made of fifty cases of chronic superficial gastritis diagnosed by means of the gastroscope Although no characteristic secretion was noted, there was a variation of the acidity from the normal value in 80 per cent of the series Hyperacidity was present in 50 per cent and anacidity in 26 per cent The higher incidence of hyperacidity in our series as compared with the figures of other authors may be explained by the fact that the more advanced forms of gastritis, hypertrophic and atrophic types, were excluded from this study The incidence of anacidity was greater among patients with gastritis than among other patients with or without gastrointestinal symptoms

Chronic superficial gastritis is characterized by a tendency toward delayed emptying of the stomach The gastric motility, judged by fractional gastric analysis, was delayed in 56 per cent of this series Patients with gastritis and achlorhydria failed to show the hypermotility usually noted with achlorhydria

Sixty-five additional patients with peptic ulcer were studied with the gastroscope in order to estimate the relation of gastritis to six hour gastric retention demonstrated radiographically The incidence of gastritis was not dependent on the presence of retention

A syndrome of duodenal ulcer was present in 26 per cent of fifty cases of chronic superficial gastritis Other symptoms were present but were not considered characteristic of gastritis Diarrhea occurred in 16 per cent and was not related to the presence or absence of acid Loss of weight was a prominent feature, being present in 46 per cent Chronic superficial gastritis is characterized by a prolonged duration of symptoms Massive hemorrhage was noted in one instance Occult blood was present in the stool in 42 per cent Foci of infection seemed to be an important concomitant observation In 86 per cent foci were present, and in the majority multiple foci existed The use of alcohol or tobacco did not seem to be an important etiologic factor in this series

## GASTROSCOPIC STUDY COMPARED WITH OTHER METHODS OF DIAGNOSIS IN GASTRIC LESIONS

ELMER B. FREEMAN, M.D.

BALTIMORE

I desire to compare gastroscopic study with other diagnostic procedures in the evaluation of gastric disease The discussion is based on the study of 200 cases and in many of these two, three or more gastroscopic examinations were made In one the gastroscope was used fourteen times A careful summary of the history, physical examination, laboratory studies and roentgen and gastroscopic observations has been made in every case The cases were not especially selected but represent a good cross section of those studied in the gastrointestinal clinic of the Johns Hopkins Hospital and the medical service of the Maryland General Hospital Some of the patients examined were not thought after study by other methods to have an organic lesion of the stomach, in other instances an organic lesion of the stomach was thought to be doubtful, and in still others a diagnosis of an organic lesion had been made by other diagnostic procedures The study really includes a group of normal subjects, a group in which the digestive symptoms were considered functional, a group in which the symptoms were thought to be due to chronic gastritis, a group with definite symptoms of gastric ulcer and a group with symptoms thought to be due to carcinoma Two groups were also studied after either pyloroplasty or posterior gastroenterostomy one in which the gastric symptoms had been completely relieved and one in which partial relief or none at all had been obtained Likewise a group of cases of unaccounted-for gastric hemorrhage were studied This group included only those cases of hemorrhage in which all the other methods of investigation had failed to disclose an organic basis for the bleeding From a comparison of the gastroscopic studies in the different groups under discussion with the results obtained by the other diagnostic methods employed, an effort will be made to evaluate the gastroscope as a diagnostic aid in the study of gastric disease

#### THE NORMAL STOMACH

Before discussing the value of the gastroscope in the study of gastric abnormalities I desire to stress the importance of the gastroscopic appearance of the normal stomach It is of the utmost importance that one be perfectly familiar with the appearance of the normal stomach, otherwise pathologic changes cannot be properly evaluated With the gastroscope introduced to full depth and in the proper position, that is, at about 10 on the clock dial, with slight inflation one will be able to obtain a good view of the pylorus and antrum in from 90 to 95 per cent of cases I am convinced that it is important to go slowly at this stage of the examination In many cases after waiting a few seconds or sometimes a little longer, one is rewarded by seeing the pylorus suddenly come into view and one can see it rhythmically opening and closing with definite regularity No change in rhythm has ever been noted in a given case While watching the pylorus, one not infrequently sees a small amount of duodenal contents

Read before the Section on Gastroenterology and Proctology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938

thrown back into the stomach. This probably does not indicate abnormality, as it occurred in some cases in which there were no digestive symptoms and in which no abnormality could be demonstrated. In two cases, with the closure of the pylorus the duodenal mucosa was seen to protrude through the pyloric sphincter into the stomach, it had much the appearance of a polyp, but in the center of the protrusion the pylorus could be distinctly seen. I am not prepared to state definitely whether this rather unusual observation is associated with symptoms, I am inclined to believe it is not. However, it may be responsible for some of the atypical symptoms that have been attributed to duodenal ulcer when ulcer could not be demonstrated by routine methods of study. When the pylorus is completely closed, the mucosa surrounding it may be thrown into folds which radiate from the pylorus much as the spokes of a wheel radiate from the hub. These folds vary in size, in some cases they are small, while in others they are large. They can scarcely be considered folds in the antial walls, as they come and go only with the opening and closing of the pylorus. Owing to the variation in the number and size of these folds, the normal pylorus when closed does not always have the same appearance. Not only can the functioning pylorus be carefully studied but the antrum may be carefully examined. The antral walls do not contain any folds. The antrum is separated from the body of the stomach by a definite fold, the musculus sphincter antri which may appear perfectly smooth but frequently has the appearance of a twisted rope. At a certain phase of peristaltic activity the musculus sphincter antri closes the antrum off entirely from the body of the stomach. As the musculus sphincter antri relaxes the antrum again comes into view and the peristaltic wave may be seen passing onward over the antrum. The mucosa of the lesser curvature is always smooth, that of the anterior wall, the posterior wall and the greater curvature is thrown into folds when the stomach is empty. The folds course the stomach in a longitudinal direction, beginning high up in the body and converging to and disappearing at the antrum. The folds on the anterior wall are small compared with those on the posterior wall and greater curvature. Branching folds are frequently seen on the posterior wall and greater curvature but rarely on the anterior wall. The size of the folds may be materially changed by inflation, that they may be almost completely effaced must constantly be kept in mind. Overinflation changes materially the gastroscopic image. The best results from gastroscopic studies are obtained with just sufficient inflation to give a clear visual field. Too much inflation interferes greatly with visualization of the antrum and pylorus.

In studying the appearance of the normal gastric mucosa, one must not forget the epoch-making experiments of Beaumont more than a hundred years ago on the stomach of Alexis St. Martin. Among other things Beaumont proved that there is a marked difference in the appearance of the normal gastric mucosa in the fasting state and in the presence of food. This observation, even though made a century ago, is still of great clinical importance and should be borne in mind in the evaluation of the gastroscopic appearance of the normal stomach. I am convinced that there are normal variations in the color of the mucosa which must be given careful consideration in determining whether there is organic disease. While a definite change in

color is important in the diagnosis of organic disease, slight variations from the accepted normal are of no real diagnostic value.

#### CHRONIC GASTRITIS

Chronic gastritis is a rather frequent disease. The etiologic relation of chronic gastritis to more serious gastric lesions especially to gastric ulcer and carcinoma, has been a subject of much discussion for several years. Hurst expressed the belief that a direct etiologic relation exists between chronic gastritis and gastric carcinoma, in that carcinoma never develops in the normal stomach but in a stomach already the seat of chronic gastritis in which atrophic changes have already occurred. Taylor stated that "the view that peptic ulcer is a sequel to an untreated gastritis in a hyperplastic stomach is rapidly commanding acceptance." If the view of Hurst concerning the etiologic relation of chronic gastritis to carcinoma and that of Taylor concerning the relation of chronic gastritis to ulcer are proved, chronic gastritis becomes the most important disease in gastric pathology. Many classifications of chronic gastritis have been discussed in the literature, some are simple and others complex. However, Schindler's classification of chronic gastritis into chronic superficial gastritis, chronic atrophic gastritis, chronic hypertrophic gastritis and gastritis following operation on the stomach is, I believe, the one best adapted to clinical use. It is true in this classification that one type overlaps the other somewhat, but this cannot be avoided in any classification.

The history, physical examination and laboratory studies may suggest the presence of chronic gastritis, but they are of no real diagnostic value. Many digestive symptoms that have been considered functional have been proved gastroscopically to be due to chronic gastritis. The physical examination may show some tenderness in the epigastric region but nothing more. The gastric analysis gives one the degree of gastric acidity. The stool may or may not show the presence of occult blood. But none of these conditions are diagnostic of chronic gastritis. The diagnosis must be made from the gastroscopic and x-ray observations, the former being by far the more important. While x-ray study is of real value in determining the size, shape, contour, peristaltic activity and motility of the stomach, it is of little value in the diagnosis of chronic gastritis beyond giving some idea as to the size and contour of the mucosal folds. On the other hand, gastroscopic study gives one the advantage of actually seeing the stomach and determining by direct inspection whether any change has occurred in the mucosa that could be attributed to chronic gastritis. In making this study, one must look for changes in the color and general appearance of the mucosa, for changes in the size and shape of the mucosal folds and for the presence and the amount of thick, tenacious mucus adhering to the gastric wall. Changes in color can be easily recognized and superficial abrasions, hemorrhagic erosions, hemorrhages into the mucosa and spots of pigment can be readily seen. Likewise the size and contour of the mucosal folds, whether small or large, edematous or nodular, can be readily determined. The amount of tenacious adherent mucus is always an important factor in making a diagnosis of chronic gastritis. Adherent mucus may be found in any type of chronic gastritis. Small or large masses of mucus found free in the stomach are of no diagnostic importance.

*Chronic Superficial Gastritis*—In chronic superficial gastritis the mucosa no longer has its characteristic normal orange red appearance but is of a much deeper red in the diseased areas. This form of gastritis may be found in any portion of the stomach, but most frequently in the body. It is frequently seen in the antrum in cases of duodenal ulcer with obstruction and delay in the emptying time of the stomach. In some cases the greater portion of the stomach seems to be involved in the inflammatory process. Usually, however, the inflammatory areas are irregularly distributed throughout the body of the stomach, occasionally one sees the inflammatory changes confined almost entirely to the antrum. The change to a deeper red is characteristic and creates a striking contrast to the normal color. One must not, however, be confused by the change in color that results from changes in the degree of inflation and in the position of the instrument. With even slight increase in the degree of inflation or slight change in the position of the instrument the area under examination may appear no longer inflamed but normal. In the antrum and to a less extent in the preantral zones, peristaltic activity may be rather troublesome. The mucosa during the peristaltic wave may show definite variations in color. The mucosa in this form of gastritis may appear slightly granular, especially in the antral and preantral zones. One may also see small hemorrhagic areas, the cause of which has not been definitely determined. The question arises: Are these small hemorrhagic areas due to trauma from instrumentation or are they a part of the chronic inflammatory process? I confess that I do not know but I believe they are part of the inflammatory process. In this type of chronic gastritis the mucosal folds are somewhat swollen and slightly edematous. They too may show small hemorrhagic areas. Small areas of tenacious adherent mucus are sometimes found, it does not occur in large amounts. It may be adherent to the antral wall, to the antral folds, to the crest of the folds in the body of the stomach or to the depths between the folds—in fact, to any portion of the stomach that is involved in the inflammatory process. There is usually some increase in the amount of secretion in the fasting stomach, and instead of the fasting contents being clear, as in the normal stomach, they may be cloudy and the mucous content definitely increased.

*Chronic Atrophic Gastritis*—Chronic atrophic gastritis is easily recognized gastroscopically. It is characterized by thinning out of the mucosa in the involved areas, with a definite change in the color in these areas from the normal orange red to a grayish green, as described by Schindler. If the atrophic gastritis is engrafted on a superficial gastritis, as frequently occurs, the contrast in color will be even greater. In determining the change in color in atrophic gastritis, as in superficial gastritis, one must be careful not to confuse again the change due to improper lighting with that due to organic changes in the mucosa. Rotating the gastro-scope from side to side may be all that is necessary to differentiation. Sometimes differentiation can be made by slight inflation, occasionally both procedures may be required before one can decide the question definitely. In the cases of atrophic gastritis that I have observed, the atrophy has occurred in the body of the stomach and not in the antrum and has always been engrafted on or associated with chronic superficial gastritis. I am of the opinion that atrophic gastritis develops only in a stomach that is already diseased.

Not only is there definite changes in color in the diseased areas, but the mucous membrane is so thinned out that the blood vessels may be easily recognized. This finding is of real diagnostic importance, as the blood vessels are practically never visible in normal gastric mucosa. Superficial abrasions and small hemorrhagic areas are frequently found—in fact, more frequently than in superficial gastritis. Large mucosal hemorrhages occur frequently—these rarely occur in superficial gastritis. The mucosal folds are much smaller and fewer in number. The atrophic changes that occur in the gastric mucosa in certain types of anemia are, I believe, entirely different from those that occur in chronic atrophic gastritis and will not be discussed in this paper.

*Chronic Hypertrophic Gastritis*—Chronic hypertrophic gastritis, as well as chronic atrophic gastritis, occurs mostly in the body of the stomach. The gastroscopic picture however, is entirely different. In atrophic gastritis the involved areas are grayish and somewhat depressed, owing to thinning out of the mucosa, whereas in hypertrophic gastritis they are much redder, and the mucosa is definitely thickened and swollen. In this form of gastritis the entire mucosa may be intensely red and angry looking, even the antrum being involved. Many abrasions and small and large mucosal hemorrhages are seen frequently, but I believe that large mucosal hemorrhages do not occur as frequently in this type as in chronic atrophic gastritis. The mucosa in some cases has a distinctly granular appearance, particularly in the preantral zone. Multiple small superficial ulcers may be found, though in my experience rarely. The mucosal folds are definitely enlarged, instead of diminished, and fewer as in atrophic gastritis. The surface of the folds is irregular and frequently nodular and sometimes polypoid. The enlarged nodular folds, the increased redness of the mucosa, the superficial abrasions, the hemorrhagic areas, the superficial ulceration and the granular appearance present a characteristic gastroscopic picture easy to recognize.

#### GASTRIC ULCER

The gastroscopic appearance of gastric ulcer, like that of the different types of chronic gastritis, is characteristic. Gastric ulcer occurs most frequently along the lesser curvature or close to the lesser curvature on the anterior or posterior wall. An ulcer occurring in the pylorus may be difficult to see gastroscopically. As stated before, the most frequent location for gastric ulcer is along the lesser curvature. The closer the ulcer is located to the antrum on the lesser curvature, the easier it is to visualize gastroscopically. An ulcer near the cardia is difficult to visualize, especially if it is located on the posterior wall. An ulcer along the greater curvature is rare. Not infrequently I have been unable to visualize clearly that portion of the stomach just below the cardia, especially the posterior wall. As yet I have not had an opportunity to study an ulcer on the posterior wall in this portion of the stomach. I am of the opinion, however, that sometimes it may be difficult to visualize an ulcer in this area, especially if it is located some distance from the lesser curvature and close to the cardia. Fortunately ulcer rarely occurs in this portion of the stomach.

It is easy to understand how the large mucosal folds on the posterior wall might completely close off the crater of the ulcer from view and thus make impossible

a gastroscopic diagnosis of ulcer in this area. When an ulcer can be properly visualized—and this can be done in nearly every case—the gastroscopic image is characteristic. The yellow or yellowish white base, the mucosal folds converging toward the crater and the edema and inflammation surrounding the crater can scarcely be mistaken for anything else. A superficial gastric ulcer may be diagnosed gastroscopically when the diagnosis is practically impossible from x-ray studies. It is scarcely conceivable that one would confuse the appearance of gastric ulcer with that of carcinoma gastroscopically.

Not only is gastroscopic study of value in the diagnosis of gastric ulcer, but it is equally valuable in determining the results of medical treatment. Observations may be made at frequent intervals, and thus one may determine the results obtained from the treatment being carried out. There can no longer be any doubt as to whether a gastric ulcer is healing under medical care, this can be definitely determined gastroscopically. In many cases reported in the literature frequent gastroscopic observations have been made throughout the entire course of treatment. These observations have proved beyond a question that gastric ulcer may heal completely under appropriate medical treatment.

#### CARCINOMA

The gastroscopic appearance of carcinoma is striking and must be seen to be truly appreciated. It is entirely different from its appearance on the operating table or in the autopsy room. In a gastroscopic study one sees the growth while it is still a part of the living organism. The growth looks entirely different *in situ* and after removal. The circulation of blood through the growth in the living state probably accounts for this difference. The gastroscopic appearance of carcinoma is entirely different from that of ulcer. In ulcer the crater or base appears yellow or yellowish white and is regular, with mucosal folds converging toward the base, and the mucosa surrounding the crater shows inflammatory changes of varying intensity. In carcinoma the ulcerative area is irregular, and sloughing black, brown or grayish tissue may be seen in the floor of the crater. Surrounding the crater the mucosal folds are markedly distorted or completely obliterated and frequently there are cancerous nodules, which vary in size considerably. This appearance is in marked contrast with that of benign ulcer. Not only does one see nodules of varying size surrounding the crater, but nodules may be seen throughout the body of the stomach in some cases, a finding which necessarily limits any operative intervention to a palliative procedure.

Gastroscopic study, I believe, will be found to be of the utmost value in the early diagnosis of carcinoma. Unfortunately one seldom sees early carcinoma. Many patients do not realize that they are suffering from a serious gastric disease until the carcinoma is well advanced, often not consulting a physician until only palliative treatment can be carried out. In another group, however, the digestive symptoms are mild, and by the usual methods of study, including history, physical examination and laboratory and x-ray studies, one is unable to find an organic basis for the symptoms. It is in this group that I am convinced that the gastroscopic method is of the utmost value. If it should be made part of the routine in the study of this group, in many cases carcinoma could be diagnosed and operated

on early in the disease, when operation offers the best opportunity of complete cure.

I am of the opinion that carcinoma can be diagnosed relatively early gastroscopically, probably before it can be diagnosed by x-ray investigations. With the fasting stomach completely emptied and the patient in the proper position, a perfectly clear view of the mucosa can be obtained, and one should be able to detect a lesion when it is too small to be located by x-ray study. If the lesion should be unfortunately located in one of the blind spots, it could not, of course, be seen gastroscopically. Owing to the location of these spots, this will rarely occur. The areas of the stomach in which malignant growth usually occurs are readily seen gastroscopically.

Any method that permits one actually to see the lesion under investigation must necessarily be of the utmost importance. By the gastroscopic method one actually sees what is going on in the stomach. It is of no value or little at most if the growth is large, and particularly when it is located on the lesser curvature and encroaches on the cardia. First, in this type of case, it may be impossible to introduce the instrument, second, if the growth is large the instrument may be so flexed that clear vision cannot be obtained. In the smooth, infiltrating type of carcinoma it is difficult to determine gastroscopically how much of the wall of the stomach may be involved. So far I have been unable to do this. Further experience, however, may enable me to do so.

#### GASTRIC HEMORRHAGE

The discussion of gastrointestinal hemorrhage will be limited to those cases in which the usual diagnostic methods failed to reveal an organic lesion to account for the bleeding—in other words, only those in which the diagnosis of an organic lesion could not be made from the history, physical examination and laboratory and x-ray studies. In this type of case gastroscopic study is of the utmost diagnostic value. The examination should be made as soon after hemorrhage has ceased as seems safe. If the examination is delayed too long, it may be impossible to determine where the bleeding came from. This is especially true if the hemorrhage is due to a superficial mucosal lesion, as I believe it nearly always is. The gastroscopic examination must be made before the lesion has had an opportunity to heal, preferably within a few days after it has occurred, otherwise the lesion may heal and no trace of the source of bleeding can be found. In this group the esophagoscope should always be used before the gastroscope. It must be constantly borne in mind that the source of the bleeding may be in the esophagus and not in the stomach, therefore it is most important to rule out esophageal disease, especially esophageal varices, before proceeding with the gastroscopic examination. Certainly one would not even attempt to introduce a gastroscope in the presence of esophageal varices. The only way to determine definitely whether esophageal varices are present is by esophagoscopy. The following brief report of a case stresses the importance of esophagoscopy in this group.

The patient had had repeated attacks of vomiting of blood and had passed black tarlike stools at irregular intervals for several years. The lower border of the liver was easily felt below the costal margin and the spleen was barely palpable. The x-ray studies showed no abnormality in the esophagus or the gastrointestinal tract. The esophagoscope showed that the bleeding was coming from varices in the lower third of the esophagus. Gastroscopic examination was not performed.

If the examination reveals no abnormalities in the esophagus to account for the bleeding, one may proceed at once with the gastrosopic study. It is important that a most thorough gastroscopic examination be carried out as it is easy to overlook the source of bleeding when it is a superficial mucosal lesion.

In a case recently studied there had been four severe attacks of gastric hemorrhage, evidenced by the vomiting of large quantities of blood and the passage of black tarlike stools at rather long and irregular intervals for five years or more. In some of the attacks, including the last one, the hemorrhage was so severe that transfusion was necessary to save the patient's life. After one of these attacks pyloroplasty was performed, the stomach was opened and a careful search for the cause of the bleeding was made, but none could be found. It was hoped that after pyloroplasty there would be no further recurrence of hemorrhage; however another severe hemorrhage occurred several months later. Three weeks after this hemorrhage the patient came under observation for the first time. An esophagosopic examination showed the esophagus to be perfectly normal. This procedure was followed immediately by a gastroscopic study which showed two rather large mucosal hemorrhages, one about the size of a nickel and the other about the size of a penny, both in the preantral zone. In the same zone there were a few superficial abrasions. The antrum appeared normal except in the pyloric region, where large mucosal folds were seen. The pylorus was patulous; the mucous membrane appeared normal, but the normal rhythmic opening and closing of the pylorus could not be demonstrated. I believe the large mucosal folds in the region of the pylorus and the altered function of the pylorus were both due to structural changes resulting from pyloroplasty. The mucosal folds on the anterior and posterior walls of the stomach appeared normal. The lesser curvature was smooth; no abnormality in this area could be demonstrated. Undoubtedly in this case the attacks of gastric hemorrhage were due to recurring superficial mucosal lesions that healed in a comparatively short time, to recur again at long and irregular intervals.

#### POSTOPERATIVE STUDIES

Postoperative gastroscopic investigation, especially if gastro-enterostomy or pyloroplasty has been performed, presents many difficulties that one does not encounter in the gastroscopic examination of the stomach that has not been operated on. The reasons for this are clear: (1) more difficulty in maintaining the proper amount of inflation, (2) regurgitation of the intestinal contents back in the stomach, and (3) changes in the appearance of the stomach as a result of the operative procedure. After posterior gastro-enterostomy or pyloroplasty has been performed it may be difficult to maintain the proper degree of inflation because the air leaves the stomach much more rapidly after these operations than normally. Regurgitation of intestinal contents back into the stomach, especially after posterior gastro-enterostomy, may be troublesome and blur the field to such a degree that clear vision cannot be obtained. When this occurs, it is better to postpone the examination for a few days. I have noticed in a number of cases that there is much less nervous tension on subsequent examinations. This may account for the satisfactory results obtained in some cases when examination is repeated. In other cases, regardless of the method used, the regurgitation is so troublesome that a clear field of vision cannot be obtained. In this small group gastroscopic examination is of no diagnostic value. Any operation on the stomach changes its contour more or less, frequently distorts the normal landmarks and materially adds to the difficulty in obtaining a completely satisfactory gastroscopic study.

My study of the stomach postoperatively has been limited to cases in which either posterior gastro-enteros-

tomy or pyloroplasty had been performed. These cases have been divided clinically into two groups, one in which the digestive symptoms had been completely relieved after the operation and the other in which only partial relief or none at all occurred. The first group showed no evidence of abnormality gastroscopically, the mucosa appeared perfectly normal. Some of these patients had had pyloroplasty, others had had posterior gastro-enterostomy. I thought that the mucosa would be normal in this group, this proved to be true. This observation agrees well with the observations of other investigators, that no evidence of chronic gastritis or other abnormality is present in the symptom-free stomach postoperatively. In the second group my studies were limited to cases in which gastro-enterostomy had been performed. Gastritis has been the most frequent cause of the symptoms so far studied in this group. The gastroscopic study may show superficial gastritis limited to a small area of the mucosa surrounding the stoma and rapidly fading out into normal mucosa. This type of gastritis may quickly respond to appropriate medical treatment. On the other hand, one may see severe hypertrophic gastritis in which the entire mucosa is involved, characterized by superficial mucosal hemorrhages, enlarged thickened nodular folds and excessive mucous secretion, with areas of adherent, tenacious mucus scattered over the greater portion of the stomach.

While the development of a marginal or a jejunal ulcer may account for the symptoms that sometimes occur after gastro-enterostomy, I do not believe that the symptoms can always be accounted for on that basis. The severity of the gastritis found sometimes in this group has convinced me that gastritis alone in some cases may be responsible for all the symptoms. The only cases in which I have seen severe gastritis following gastro-enterostomy have been those in which there was no evidence of pyloric obstruction roentgenologically, the barium leaving the stomach about as rapidly through the pylorus as through the stoma. What etiologic relation the gastro-enterostomy bears to the gastritis I am unable to state, but I do believe that in certain cases the altered function of the stomach resulting from the gastro-enterostomy, in the presence of a patulous pylorus, is in some way responsible for the gastritis. Further gastroscopic observations will be carried out in this group in an effort to determine definitely this relation, if any. I have seen patients after gastro-enterostomy who had no pyloric obstruction but had symptoms of chronic gastritis which were promptly relieved after the gastro-enterostomy had been undone and the normal continuity of the gastrointestinal tract reestablished.

#### SUMMARY AND CONCLUSIONS

Gastroscopic studies have been made in 200 cases, in many, two or more examinations were made, the total number of examinations being 325. From these studies I believe one is justified in making the following deductions:

- 1 The procedure is helpful diagnostically in the study of gastric disease.

- 2 It bears a supplementary relation to the other diagnostic methods employed in the study of gastric lesions, it does not replace any one of them.

- 3 Before attempting the gastroscopic study of pathologic conditions, one should thoroughly familiarize oneself with the normal variations in the appearance of the stomach so that these will not be confused with variations due to organic disease.

4 In the study of the different types of chronic gastritis I believe that the gastroscope has its greatest field of usefulness. Inflammatory changes in the gastric mucosa can be studied more carefully gastroscopically than by any other diagnostic method.

5 In the diagnosis of gastric ulcer, gastroscopic study is of real value. I am not at all convinced, however, that one can always find an ulcer if it is located on the posterior wall near the lesser curvature. I observed a case recently in which x-ray study showed a definite niche on the lesser curvature, somewhat closer to the cardia than to the pylorus. I was unable to find an ulcer gastroscopically.

6 Gastroscopic study in the diagnosis of carcinoma, especially in the early stages, will be found to be of the utmost value. I believe one should be able to find carcinoma gastroscopically before it can be found roentgenologically. Unfortunately, one seldom sees an early carcinoma. The disease is usually well advanced before the patient himself realizes he needs medical care.

7 Gastroscopic study will often reveal the source of bleeding in obscure gastric hemorrhage and should always be done in cases of undetermined gastrointestinal bleeding.

8 In the postoperative study of the stomach in which symptoms have recurred or in which they have not been completely relieved, the gastroscope is helpful. It may reveal that the symptoms are due to a marginal or a jejunal ulcer, but from observations so far made I believe that in some cases, at least, the symptoms are due to chronic gastritis of varying degree and not to the presence of either a marginal or a jejunal ulcer.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRs BANK AND RENSHAW  
AND DR FREEMAN

DR ROBY JOHN F. RENSHAW, Los Angeles. The comparison of gastroscopic study with other methods of diagnosis is fraught with danger because there are so many variable factors: the skill of the gastroscopist, the experience of the radiologist and the pathologist's conception of gastritis are but a few. Dr Freeman has surveyed the problem, and I think he has arrived at conservative conclusions. His beautiful slides portrayed the problem more dramatically than is possible verbally. His point that one must be familiar with the normal stomach is the most important part of his paper. It has been my experience to hear men condemn gastroscopic examination because of a diagnostic failure, but they have not taken into consideration the examiner's skill or the particular difficulty in that case. Gastroscopists are going through the same process that cystoscopists and radiologists did some years ago. We are establishing our procedure and our normals. Today the physician will interpret a diagnostic failure in radiology—in terms of the radiologist's skill and the particular difficulties in that case—but often that is not true of his criticism of the gastroscopic method. In a consideration of gastroscopic study as related to other procedures the comparative ease or difficulty should be considered. I am not convinced that the gastroscope is safe in awkward hands. I believe that the gastroscopist should be skilled and trained in the passage of that instrument and should possess a delicate sense of touch; furthermore, he should have a trained assistant. If these conditions are fulfilled, gastroscopic study is a safe and simple procedure; furthermore, if one takes reasonable care to exclude contraindications, I see no reason to consider it a dangerous procedure as some men have. I have not been able to find a single case in the literature, nor do I personally know of one, of death resulting directly from the gastroscopic procedure.

DR MILFORD O. ROUSE, Dallas, Texas. As Dr Freeman mentioned, the use of the flexible gastroscope offers a way of more positive differentiation of gastric lesions manifesting them-

selves as x-ray filling defects, as well as of accurate diagnosis of the presence of foreign bodies in the stomach. I have a case on the point in question. Fluoroscopic study and roentgenograms of a patient's stomach showed a marked filling defect in the stomach, immobile and not palpable. Gastric acidity was normal, with occult blood present. My partner, Dr C. O. Patterson, examined the patient with the gastroscope and beheld a black cylindric mass which he diagnosed as a phytobezoar, or so-called persimmon ball. Operation was advised and done the day before I left. The specimen removed on surgical exploration weighed 171 Gm and was of pretty fair size. It was of value to know beforehand that we were dealing with a foreign body and not with an extensive malignant growth, as this might have indicated. The gastroscope should be utilized and mastered by the gastroenterologist rather than by the otolaryngologist, the general surgeon or the general practitioner with a flair for taking up something new. The otolaryngologist can deftly pass the instrument, but he is like a surveyor or landscape architect in describing what he sees. His training and interest do not permit him to interpret what he sees, but gastroenterologists are more like medical geologists; we can both see and interpret what we do see, and so the burden and privilege of advancing gastroscopic practice lies with the members of this section.

DR P. E. T. HANCOCK, London, England. I much appreciate the honor of being allowed to take part in this discussion on the excellent papers of Drs Bank and Renshaw and Dr Freeman. My experience with the gastroscope is limited to some 400 instrumentations extending over two and a half years in London. Drs Bank and Renshaw have done valuable work in correlating the gastroscopic appearances with the acidity and the emptying time of the stomach. They have confined their paper, I think wisely, to one type of gastritis, namely chronic superficial gastritis. In my experience the gastroscopic observations do not correspond with the pathologic picture. My experience extends to some fifty cases in which I have used the gastroscope and in which gastric resection has followed the gastroscopic study, in over half of those I noted extensive gastritis of one type or another. On serial section of the resected stomachs the pathologist was able to show gastritis in most cases, but the type of gastritis did not correspond with the type I had noticed. Particularly was that true of the hypertrophic type, which is commonly seen and is a definite entity gastroscopically, but in none of those fifty cases was any true hypertrophy demonstrable pathologically. Hypertrophic gastritis is recorded so commonly that Henning found 50 per cent of all gastritis to be hypertrophic. I believe a normal must be established, gastroscopically and histologically. The criteria of normal for the stomach are difficult to obtain. In all stomachs apparently there are slight pathologic changes, and to correlate the gastric normal with the histologic normal is, I think, important. I believe gastroenterologists should try, in all cases in which the gastroscope is used, to make careful notes not only on the lesions but on the entire gastric mucosa. We should then be in a position to compare the appearances noted gastroscopically with serial sections of the gastric mucosa and establish this important correlation.

DR JOHN H. FITZGIBBON, Portland, Ore. Although neither speaker dealt with technique, I should like to ask two questions regarding technique, as there are a number of gastroscopists present who may be interested in the answers. I should like to know whether either of the speakers gave atropine before the examination. I have long since discontinued its use because I am able to see active peristalsis in practically every case without atropine, which enables me to get a better view of the lesser curvature of the antrum. The second question is regarding the local anesthetic used. I have used 2 per cent pontocaine hydrochloride in practically every case and have seen four serious reactions. I should like to know whether either of the speakers has had a similar experience. Approximately 13 cc of the solution was used in each case. The reactions have started with what the patient described as a peculiar feeling in one ear, followed by dizziness, loss of equilibrium and marked nystagmus.

DR FREDERIC E. TEMPLETON, Chicago. During the last four years I have had the opportunity to examine roentgenologically most of the patients studied with the gastroscope by Dr Rudolph Schindler. Dr Freeman has emphasized the blindspots in the

stomach which may hide various lesions. In a recent comparison Dr Schindler and I found that in about equal numbers of cases the gastric ulcer could be seen only roentgenologically and only gastroscopically. Occasionally Dr Schindler has had the experience of seeing an ulcer at one examination but not at a subsequent examination. Yet this phantom-like ulcer was always evident at roentgen examination. The reverse was also true—i.e., an ulcer always seen gastroscopically was not seen at every roentgen examination. I am not entirely convinced that the gastroscope can detect a gastric carcinoma earlier than can the x-rays. On the surface this seems likely, but there have been few cases in which Dr Schindler has diagnosed carcinoma missed with the x-rays. In these cases I have been able, by using careful mucosal technic at reexamination, to convince myself of the presence of the lesion. On the other hand, I have seen carcinomas not seen by the gastroscopist. When one speaks of comparing the two methods, the technic and difficulties of the gastroscopic procedure must be considered. If the gastroscopist can see the lesions he can usually diagnose them, but there are places in the stomach, sometimes rather large, that are hidden, therefore it should be emphasized that the two methods are cooperative and not competitive. I should like to ask Dr Freeman whether he has seen carcinomas or ulcers not seen by the roentgenologist.

DR JOSEPH BANK, Phoenix, Ariz. To answer the question of Dr Fitzgibbon, we use atropine and codeine preliminary to anesthesia of the throat in gastroscopic study. Dr Renshaw and I feel that atropine is of some value because it reduces the amount of salivary secretion, making the examination easier. Regarding pontocaine hydrochloride, we have not observed any accidents or ill effects. I don't believe that Dr Schindler has either. There have been deaths from pontocaine hydrochloride one in this country and eight abroad. However, in eight of the nine cases the preparation was used in association with bronchoscopic study and urethral instrumentation in which the examiners used larger quantities than we do. We use 10 cc, in two instillations of 5 cc each.

DR ELMER B. FREEMAN, Baltimore. In reference to the local anesthetic, I have used either 10 per cent cocaine or 2 per cent pontocaine hydrochloride. I have had no untoward effects from either. However, I have not had a great deal of experience with pontocaine hydrochloride having used cocaine as a routine until just recently. In preparation of patients for gastroscopic study 2 grains (0.13 Gm.) of phenobarbital is given at bedtime the night before and 2 grains (0.13 Gm.) two hours before the examination. I have seen no advantage in using atropine. As to whether I have been able to diagnose carcinoma earlier with the gastroscope than with the x-rays, I am frank to say that I have not. Unfortunately, one rarely sees an early carcinomatous lesion, the patient himself not realizing that he needs medical attention until the disease is well established. In the body of the paper the importance of routine gastroscopic study in a certain definite group of cases has been thoroughly discussed. I firmly believe that if gastroscopic examination was made a routine in this particular group one would be able to diagnose carcinoma in some cases at an earlier stage than is possible roentgenologically.

**County Health Departments in Kentucky**—For generations the responsibility for the health and medical care of the people of Kentucky has been placed, by law, squarely on the shoulders of the medical profession. All the policies and practices of the department of health are approved by the medical profession of the state. We not only have a splendidly organized and equipped central state department but ninety-one of our counties are now provided with full-time county health departments which are within reach of all the people with the scientific knowledge that means better health, longer life and increased efficiency. This has all been brought about by long time administrative planning in which the medical profession has taken the leadership and in which they have secured the fine cooperation of dentists, public health nurses, pharmacists, sanitary engineers and educators together with the great organized farm groups—the Federation of Women's Clubs, the Congress of Parents and Teachers and the great labor organizations.—Radio address by Gov. A. B. Chandler Dec. 6, 1938.

## REGULATION OF THE LEVEL OF CALCIUM IN THE SERUM DURING PREGNANCY

MEYER BODANSKY, PH.D., M.D.

AND

VIRGINIA B. DUFF, M.A.

GALVESTON, TEXAS

The maintenance of a uniform level of calcium in the serum was called by Cannon<sup>1</sup> an example of physiologic homeostasis. The regulation depends on a combination of factors, chief of which are function of the parathyroid, calcium intake, utilization and excretion, and the availability of a mobilizable calcium reserve.

In considering the subject as it applies to pregnancy it becomes apparent that each of these factors assumes even greater importance than ordinarily; moreover, other relations enter into the picture to make it even more intricate. A significant fact is that the calcium level tends to decline during the later months of pregnancy. The conception that this is related to the withdrawal of calcium for fetal development is only partly tenable; it does not explain, for example, why low values occur in women with a good nutritional history whose mineral intake during pregnancy is more than sufficient to meet both the maternal and fetal requirements.

Just what significance is to be attached to the low serum calcium values is not clear. Are the concentrations subnormal in the true or absolute sense, or is there the possibility of somewhat different normal values for pregnant and for nonpregnant women? If the lowered calcium content is looked on as abnormal in the same way as a low hemoglobin value in anemia of pregnancy is abnormal, then the change probably reflects some deficiency in respect to the calcium intake or parathyroid function, or possibly some other factor. On the other hand if the normal pregnancy level is conceived to be distinct from the normal nonpregnancy level, it would be necessary to seek an explanation for the lower level either in coincidental and related changes in the blood, or in some fundamental differences in the underlying regulatory mechanisms. A unified conception of the regulation of the calcium content during pregnancy must also take into account the relations between the maternal and fetal organisms. In the following discussion consideration will be given to two coincidental changes which could conceivably influence the calcium content, namely (1) dilution of blood and (2) protein concentration in serum. An attempt will also be made to analyze in the briefest possible form the specific roles of factors governing calcium metabolism, which may be supposed to affect the maternal organism, primarily, (3) parathyroid function, (4) calcium intake, (5) seasonal effects, (6) effects of hormones other than the parathyroid. The fetal-maternal relationship will be outlined briefly from the standpoint of the concentration of calcium in the blood on the two sides of the placental barrier and the influence of the calcium level on fetal development.

Acknowledgment is due to the board of the Sealy and Smith Foundation for their generous grant.

From the John Sealy Memorial Research Laboratory and the Department of Pathological Chemistry, University of Texas School of Medicine. Read before the Section on Pathology and Physiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

## DILUTION OF BLOOD

Dieckmann and Wegner<sup>2</sup> have estimated that at term the volume of blood is increased 23 per cent and the volume of plasma 25 per cent above normal. The analyses of Oberst and Plass<sup>3</sup> showed a rise from an average of 909 to 914 Gm of water per kilogram of plasma, followed by a decline to 906 Gm at delivery. There is, however, a wide range of variation in the various groups with an overlapping of data. Dieckmann and Wegner<sup>2</sup> found the conductivity of the serum at term to be from 4 to 6 millimols below normal, it did not return to normal until from six to eight weeks post partum.

An examination of these and other data does not reveal any significant correlation between the changes in water content of the serum and the calcium concentration. It seems improbable that dilution of blood or the small changes in the water concentration of the plasma, which incidentally differ in protein from the changes in calcium content, could be fundamentally involved in the differences under consideration.

## PROTEIN CONCENTRATION IN SERUM

The proteins in the serum also tend to decrease during pregnancy. Dieckmann and Wegner<sup>2</sup> found the average concentration at term to be 7 per cent below that during the first trimester. A further decrease was

TABLE 1—Calcium Level of Pregnant Rats at Term

	Number of Animals	Calcium Mg. per 100 Gm. of Serum			
		Max.imum	Min.imum	Average	Standard Deviation
Normal	13	11.0	8.2	9.7	0.9
Parathyroid deficient	10	7.4	1.1	5.1	1.12

Diet 7 of Cox and Imboden<sup>18</sup> (calcium 0.19 per cent and phosphorus 0.4 per cent) was given.

noted during the first few days post partum, this was followed by a slow rise to normal at about eight weeks. This trend differs from the changes in calcium concentration, which begins to rise soon after labor and is usually restored to the nonpregnancy level within six to fourteen days post partum.

Further clarification of this point is necessary in view of the evidence that the total protein and calcium concentrations are proportional. The relation has been expressed by empirical regression equations (Hastings, Murray and Sendroy,<sup>4</sup> Greenwald,<sup>5</sup> Peters and Eiser-son,<sup>6</sup> McLean and Hastings<sup>7</sup> and others). A more precise formulation has been attempted recently by the Gutmans<sup>8</sup> in which the total calcium is related to the concentrations of albumin and two globulin fractions. However, it seems that these equations do not apply if there is a primary disturbance in calcium metabolism or in the presence of hyperphosphatemia. From the

data of Oberst and Plass<sup>3</sup> it would appear that these equations also do not hold in pregnancy. Their results showed that the significant correlation between protein and calcium concentrations in nonpregnant and puerperal women is completely lost in late pregnancy and parturition, when the protein range is considerably widened. This lack of correlation, partly confirmed in our studies, sets pregnancy apart from the normal condition, in which there is a predictable relationship between total calcium and protein values. Since hyperphosphatemia may be excluded, there remains only the alternate explanation of a primary disturbance in calcium metabolism. Whether this view is tenable in its entirety or not, the conclusion nevertheless seems justified that effects on the calcium content referable to a change in protein concentration are doubtless overshadowed by other factors.

## PARATHYROID FUNCTION

In the absence of disorders of the parathyroid glands variations in total protein are accompanied by changes in total calcium, the result being approximate constancy of the calcium ion concentration (McLean and Hastings<sup>7</sup>). Deficiency of hormone leads to a reduction in  $\text{Ca}^{++}$  concentration while hyperparathyroidism is accompanied by an increase. The importance of the parathyroid glands in maintaining a constant calcium level in the plasma has been related to a direct action of the hormone on the bone cells, resulting in the production of osteoclasts and the release of calcium (Thomson and Collip<sup>9</sup>). Bauer, Aub and Albright<sup>10</sup> have submitted evidence that the trabeculae of the bones contain the mobilizable reserves. On the other hand, Aaron Bodansky and Jaffe<sup>11</sup> have shown that the most recently formed bone, in whatever site, is the bone most readily dissolved.

It is conceivable that parathyroid stimulation during pregnancy could result from absolute or relative calcium deficiency, the tendency to hypocalcemia and the necessity of maintaining a more active calcium metabolism than ordinarily. Although this conception is logical, the evidence for it at present is fragmentary. It is practically limited to the histologic observations of Seitz<sup>12</sup> and the experiments of Hoffmann and Rhoden<sup>13</sup> and Hamilton and associates,<sup>14</sup> who found that the blood of pregnant women contains a substance which behaves like parathyroid hormone in elevating the calcium level of the blood. However, it is hoped that experimental studies now in progress in our laboratory (Sinclair and Bodansky<sup>15</sup>) will provide adequate proof of parathyroid enlargement as a normal concomitant of pregnancy.

Evidence of the participation of the parathyroid glands is to be found also in roentgenograms of the bones. In rats with intact parathyroid glands, kept on low calcium rations through one or more pregnancies, demineralization of the long bones is much more pronounced than in animals deprived of these glands, in the

latter the bones show little, if any, change in density. As will be shown presently, the calcium content in the first group is maintained at approximately the normal level, whereas in the second group it invariably declines, often below 5 mg per hundred cubic centimeters. The explanation is obvious. Calcium deficiency in the normal pregnant animal produces parathyroid stimulation, calcium is withdrawn from the bones in order to maintain the concentration in the blood above the tetany level. On the other hand, with the abolition of this regulatory mechanism in the parathyroid-deficient organism, the calcium level is progressively lowered as pregnancy advances, loss of body calcium is probably reduced thereby, and the calcium reserves are spared.

The frequency of low calcium in the values for serum and borderline manifestations of tetany (Chvostek phenomena and increased excitability to galvanic stimulation) in gravid women directs attention to the possibility of parathyroid insufficiency as a disturbing factor in pregnancy. In cases of this sort it is usually difficult to establish with any degree of certainty the relative importance of nutritional and hormonal factors in the production of hypocalcemia and the attendant symptoms. However, it may be argued that, dietary deficiency notwithstanding, the development of hypocalcemia is in itself evidence of an inadequate parathyroid response and consequently represents a condition of relative hypoparathyroidism. At the same time it must be realized that the parathyroid glands can be expected to accomplish just so much in the homeostatic control of the calcium level of the serum and not more. As the bones are depleted of their more readily mobilizable calcium reserves it must become increasingly difficult to maintain the calcium in the serum at the normal level.

The rise in the phosphatase content of the serum in pregnancy (Meranze and his associates,<sup>16</sup> Bodansky, Campbell and Ball<sup>17</sup>) is consistent with augmented parathyroid function, but since the phosphatase level may be influenced in other ways this rise must be interpreted with caution. This question will receive further attention elsewhere.<sup>18</sup>

Depression of the calcium concentration in the serum below 9 mg occurred frequently in our study of over 300 pregnant women, yet it was impossible to select from this group any persons in whom the hypocalcemia could be unequivocally attributed to parathyroid insufficiency. We are therefore obliged to draw on our experimental material in order to illustrate the importance of the parathyroid glands in governing the calcium level during pregnancy.

In table 1 are summarized the results obtained for a group of animals kept on a diet with a calcium-phosphorus ratio of 1 and a calcium level of 0.49 per cent. This diet has been adjudged, on the basis of weight of the young at 21 days, ash content of the young and change in weight of the mothers, to be the ideal mineral level and ratio for successful gestation and lactation in rats (Cox and Imboden<sup>18</sup>). Parathyroid-deficient rats kept on such rations become pregnant and apparently thrive until toward the end of gestation. From two to four days before term slight tremors of

the paws develop, these being more apparent when the rat is held up. The tremors become progressively more pronounced, the body is stiffened and the tail becomes rigid. The rat moves stiffly and with apparent difficulty even on a flat surface. Anorexia is a prominent symptom. Despite these severe manifestations the rat may improve, go through delivery and recover. Or the downward course may proceed in one of two ways. Rarely, the tremors become more and more severe, ultimately assuming tetanic convulsive proportions, the rat loses consciousness and death occurs rather rapidly. These stages consume in all about twelve to eighteen hours. Much more commonly the tremors cease, the rat becomes more and more quiescent and then lethargic. It can be roused only by pronounced stimuli. Meanwhile the body temperature drops, and finally the rat dies effortlessly.

These events may commence after the onset of labor (appearance of blood at the vagina). As a rule death occurs before any of the young have been delivered, but occasionally it may follow the delivery of part of the litter. A few of the animals in our series died after completing delivery, but in these labor was markedly prolonged (from one to two days). In parathyroid-deficient rats the onset of labor is frequently delayed beyond the normal gestation period, which is from twenty-one and one-half to twenty-two days. As a rule the duration of labor is also prolonged.

Such manifestations have never been observed in rats which have not been operated on. Among several thousand pregnancies and deliveries in our colony during the last five years only three maternal deaths have been recorded.

The combination of pregnancy and parathyroid deficiency favors the development of the low concentrations of calcium in the serum recorded in table 1. In contrast to these data the calcium content is easily maintained in the neighborhood of 6 mg or higher in non-pregnant parathyroidectomized rats kept on an adequate diet. The drop from the higher to the lower level of hypocalcemia probably accounts for the effect of pregnancy in converting latent into active tetany in parathyroid (and thyroparathyroid) deficient animals, as reported by previous observers (Halsted,<sup>19</sup> Carlson,<sup>20</sup> Werelius,<sup>21</sup> Luckhardt and Rosenbloom,<sup>22</sup> Bodansky and Cooke<sup>23</sup>).

As a rule the offspring of parathyroid-deficient mothers are much smaller than normal.

An effective way to combat the effects of parathyroidectomy in rats is by raising the calcium level of the diet to 1.225 per cent and reducing the phosphorus content to 0.245 per cent (diet 16 of Cox and Imboden<sup>18</sup>). On this diet the calcium concentration of the serum at term was either normal or elevated and littering was invariably successful. However, when in any of these animals in a subsequent pregnancy the levels of calcium and phosphorus intake were altered to those of diet 7, which as we have indicated is the optimal diet for reproductive success in the normal rat on whom no operation has been performed, hypocal-

cemia developed at the termination of pregnancy and was attended by the symptoms that have been described. A summary is given of a protocol for a typical experiment.

#### Summary of Protocol of Rat MJ-71

11/12/36	Weight 228 Gm age 150 days, parathyroidectomized
11/24/36	Changed from stock diet to diet 16 of Cox and Imboden <sup>24</sup>
11/9 12/36	Mated
1/2/37	Delivered litter of eight weighing 44 Gm Weight of mother after delivery 230 Gm
1/16/37	Infertile mating
2/1 2/37	Mated
2/23/37	Delivered litter of nine, weighing 45 Gm, calcium level during labor 10.8 mg, maternal weight after delivery 252 Gm
2/27/37	Changed to diet 7 of Cox and Imboden <sup>24</sup>
2/27 3/6/37	Mated
3/27/37	Rat weighed 326 Gm and was due to deliver
3/29/37	Rat lost weight (to 314 Gm), was at least two days overdue was in severe tetany with blood at the vagina but failed to deliver. Bled to death. Uterus contained litter of nine all alive weighing a total of 28.5 Gm. Serum calcium content 3.4 mg.

#### CALCIUM INTAKE

The calcium balance may be maintained in the normal nonpregnant, nonlactating woman on a calcium intake of about 0.5 or 0.6 Gm daily. However, during the later months of pregnancy the daily calcium require-

Hypocalcemia of this degree results from severe calcium deficiency continued throughout the period of gestation superinduced on a shortage in the calcium reserve at the onset of pregnancy. Although the combination represents an extreme form of calcium deficiency perhaps never encountered in the United States, we may nevertheless inquire whether the less marked but more common degrees of hypocalcemia do not likewise reflect calcium deficiency, though obviously of less severity. It seems, however, that this interpretation has been generally avoided by other writers.

In relation to the normal standards for nonpregnant women calcium concentrations below 9 mg are definitely subnormal. It is therefore significant that fully 50 per cent of the women examined by Plass and Bogert<sup>29</sup> during the last five months of pregnancy showed calcium levels below 9 mg. Such low values were much less frequently recorded in Mull and Bill's analyses.<sup>30</sup> In our studies (Bodansky, Campbell and Ball<sup>31</sup>) the highest incidence of subnormal calcium values (less than 9 mg per hundred cubic centimeters) occurred in the ninth lunar month, when it comprised 24 per cent.

It was not possible to relate all the low values to dietary calcium deficiency nor were all of the concentra-

Diet 7 of Cox and Imboden<sup>24</sup> (calcium 0.4% per cent and phosphorus 0.49 per cent) was given.

ment increases to about 1.5 to 2 Gm (Coons and her associates,<sup>32</sup> Lovcrud,<sup>33</sup> Macy<sup>34</sup>). The dietary habits of a large proportion of women do not change sufficiently during pregnancy to assure the higher level of intake (Coons,<sup>34</sup> Sontag<sup>35</sup>) and consequently considerable variability in nutritional status may be expected. The extent to which the calcium concentration of the serum is influenced by the amount of calcium in the food is obviously a question of much importance.

The lowest values that have been reported in human subjects which may be definitely attributed to calcium deficiency were those obtained by Maxwell<sup>28</sup> in his study of osteomalacia among pregnant Chinese women. He found that the daily calcium intake among the poorest patients was often as low as 0.1 to 0.2 Gm a day. In these women tetany regularly developed at term, the calcium content declining to as low as 3.6 mg per hundred cubic centimeters.

tions above 9 mg in persons receiving an adequate diet. From these observations and from our experimental studies on the rat it seems that for a considerable range of calcium intake, not excluding moderate grades of deficiency, the calcium content of the serum is relatively unaffected. This is partly in accord with the conclusion of Pyle and his associates,<sup>31</sup> that the level of calcium in the food has little effect on the calcium level of the blood. We believe, however, that, barring parathyroid deficiency, values below 8.5 mg, and certainly below 8 mg, are essentially the result of calcium and of vitamin D deficiency.

#### SEASONAL EFFECTS

Mull and Bill<sup>30</sup> found that the values for calcium in the serum for all stages of gestation were on the average higher from June to December than from January to May. We have charted our results according to the month of the year and the month of gestation (fig. 1). The average values for calcium began to decline in November and reached a minimum during

offspring of normal and parathyroid-deficient rats. The latter are almost invariably smaller than normal and are otherwise retarded in development. Frequently, though not invariably, the ash content and especially the calcium content are low (table 2). It would seem that these abnormalities are specifically related to the hypocalcemia in the mothers and the consequent low calcium level of the fetal circulation.

#### CONCLUSIONS AND DEDUCTIONS

If the difference in the calcium concentration of the blood on the fetal and the maternal side of the placental barrier were explained, it would contribute materially to a fuller comprehension of the regulation of the calcium in the blood during pregnancy. First, it is necessary to reconcile the depressed calcium level in the maternal circulation with the apparent increase in maternal

guesses as pregnancy advances and is relieved soon after it is terminated, may be dependent on some intrinsic factor. It is logical to look to the placenta as the possible source of such a substance. Tangible evidence is lacking, however, since the results obtained so far have lacked uniformity. While certain observers (Frommer,<sup>40</sup> Mathieu<sup>46</sup>) have induced active tetany in animals with latent tetany (question of calcium depression), others have recorded a calcium-elevating effect (Bomskov and Bremm,<sup>40</sup> Peritz<sup>44</sup>).

It has been found that in the cow the fetal part of the placenta, especially early in pregnancy, is richer in calcium than the maternal part (Fenger<sup>45</sup>), from which it may be generalized that the fetal placenta serves as a reservoir of calcium, mobilizable perhaps by the fetal parathyroid gland, or by some other mechanism, for use in fetal development of bone. Work now in progress prompts us to suggest that a relative elevation of fetal serum calcium may be desirable, promoting normal fetal development of bone.

Bakwin<sup>46</sup> in a recent discussion of tetany in the newborn explains the tendency to hypocalcemia and the attendant hyperphosphatemia on the basis of hyporeactivity of the parathyroid glands at birth. It is, however, conceivable that another factor in the causation of hypocalcemia in the newborn may be the withdrawal of the labile calcium reserve of the fetal placenta. There is the additional possibility, however remote, that in acquiring independent existence the newborn infant is deprived of some other placental factor which in intra-uterine life helps to maintain the higher calcium level.

Figure 2 represents an attempt to integrate tentatively, the known and hypothetical relations involved in the regulation of the calcium level, particularly in the maternal circulation. It is presented at this time primarily for the purpose of indicating the direction for future research.

#### SUMMARY

Within certain limits (not lower than 8.0 mg) the depression of calcium in the serum observed in late pregnancy may be considered a normal condition, conducive perhaps to a greater economy of utilization of calcium derived from food and maternal bodily reserves.

Severe hypocalcemia during pregnancy may reflect either parathyroid deficiency or marked nutritional deficiency. Both are comparatively rare in ordinary clinical experience. The importance of the parathyroid glands in the regulation of the calcium content becomes especially impressive in the parathyroid-deficient pregnant animal at term.

Abnormalities in fetal skeletal development occur if hypocalcemia is severe, as shown by the results in experimental parathyroid deficiency and in clinical osteomalacia (Maxwell's studies<sup>28</sup>). The somewhat elevated calcium level in the fetal circulation may therefore be looked on as normal for fetal development.

Nutritional, hormonal and seasonal factors influence the maternal calcium level. The influence of season may be only partly related to the amount of available sunshine.

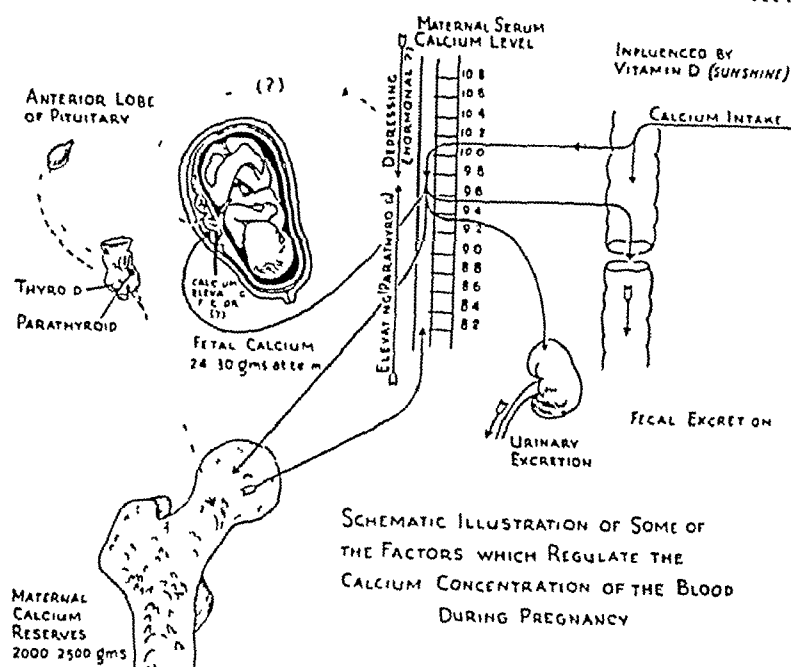

Fig. 2.—The solid lines indicate migration of calcium; the broken line hormonal influences.

parathyroid activity. Second, an explanation must be found for the elevated calcium level of the fetus, which presumably receives no parathyroid hormone from the mother (Hoskins and Snyder<sup>43</sup>) and in which parathyroid function is generally thought to be held in abeyance.

It is relevant to point out that the difference between the maternal and the fetal calcium level is independent of the protein content, which is in fact lower on the fetal than on the maternal side of the placental barrier. Physicochemical considerations based on distribution of protein cannot be invoked, therefore, to explain the difference.

A significant observation is that after birth the calcium content of the mother rises, whereas that of the offspring declines, often abruptly.

We may look on a moderately lowered calcium level in the gravid organism as a normal and, within limits, even a desired condition, conducive perhaps to a greater economy of utilization of the dietary and reserve calcium. Accordingly, it is possible that the depression in the calcium content of the maternal blood, which pro-

It is possible that in pregnancy the maintenance of a subnormal calcium level in the maternal serum, as judged by nonpregnancy standards, despite the augmentation in parathyroid function, is dependent on an intrinsic calcium-depressing factor. The maintenance of a relative elevation of calcium in the fetal serum may also indicate the participation of some factor in the fetal organism independent of the fetal parathyroid glands. The rise in the maternal calcium level after parturition and the decline in that of the newborn infant suggest that these factors may reside in the maternal and fetal portions of the placenta respectively, each playing a distinct and important role in the regulation of the maternal and the fetal calcium level. The decline in calcium content observed in the newborn may also be conditioned by the sudden withdrawal of the labile calcium reserve of the fetal placenta.

## Clinical Notes, Suggestions and New Instruments

### TEMPORARY COMPLETE CONTROL OF THE MAIN BLOOD SUPPLY AS A PRELIMINARY STEP IN DIFFICULT SPLENECTOMIES

EDWIN M. MILLER, M.D., CHICAGO

Splenectomy may be a very simple or a very hazardous procedure. I have found that a difficult splenectomy may be much simplified by complete control of the main blood supply as the first step in the operation. With the stomach emptied by aspiration immediately before operation, the lesser curvature is easily

Simple and effective means of temporarily shutting off practically all of the blood supply to the spleen during difficult splenectomies

retracted downward toward the left and the tortuous splenic artery is identified close to its origin (b). A piece of small soft rubber tubing is then passed around the artery at this point and an artery forceps is placed across the tubing so as to shut off completely the main blood supply during the operation (c). Immediately the huge spleen can be seen to diminish greatly and one may then proceed with splenectomy in the usual way, without fear of hemorrhage. After the spleen has been removed and the vessels at the pedicle have been securely tied off, the rubber tubing is removed from the splenic artery.

Actual ligation of the splenic artery has often been done as a substitute for splenectomy and for many years has been carried out as a preliminary step during splenectomy, but such a procedure may deprive the pancreas of a considerable amount of its blood supply if performed very near the coeliac axis and if

done near the tail of the pancreas, may be technically difficult. I have therefore chosen to employ this very simple and effective means of temporarily shutting off practically all the blood supply to the spleen and thus making difficult splenectomies relatively simple procedures.

### ESOPHAGEAL OBSTRUCTION RESULTING FROM AN INJUDICIOUS METHOD OF INGESTING A HYGROSCOPIC GUM LAXATIVE (SARAKA)

ESOPHAGOSCOPIC REMOVAL

MANFORD REPP WALTZ, M.D., SEATTLE

In the practice of medicine and surgery, emergency conditions arise that call for treatment though the conditions have never been seen before, but if similar conditions have been reported by others and the means of handling them have been described, they become much simpler. It is for this reason that I am reporting a case of sudden esophageal occlusion due to the ingestion of Saraka, a hygroscopic gum laxative, which resulted in an extremely uncomfortable and progressive condition because of its progressive swelling.

Mrs. H. B., aged 59, had been taking Saraka as a laxative. She took 1 or 2 drachms (4 or 8 Gm.) each day by putting a drachm on the back of her tongue and helping it down with a glass of water. She did not object to the taking of the Saraka but considered it as a means to an end (relieving constipation). Nov. 16, 1937, she hurried things along by swallowing 1 drachm and immediately swallowing the second drachm with only a small amount of water.

Almost immediately after swallowing the second drachm she experienced the sensation of obstruction, inability to swallow, some substernal pain which increased as time progressed and a feeling of fullness and distention as though her insides were being forced apart. Water was tried but was immediately regurgitated. Dr. J. H. Berge, who was called, sent the patient to the Seattle General Hospital and called me in. He stated the facts of the case as reported and told me that Saraka is a gum laxative which cannot be dissolved except with inorganic acids—information given to him by his druggist. He also stated that an article in *THE JOURNAL*<sup>1</sup> had reported a case in which the Saraka had been removed by breaking up the mass and scooping it out through an esophagoscope.

Not having time to find and review the article I experimented with Saraka before seeing the patient. I found that it could not be aspirated through the regular esophageal aspirating tube but that it could be aspirated through a stiff rubber tube which would just fit a 10 mm. esophagoscope. Our decision was to try this and then break up the mass if necessary with a forceps. This procedure worked beautifully until a mass which later proved to be 1 inch (2.5 cm.) in diameter by 1 3/4 inches (4 cm.) in length remained as a plug at the cardia. This could not be broken up but was movable; the aspirating tube going all the way around it. In desperation I forced the end of the instrument against the mass and applied the end of the aspirating tube against the mass and gently pulled esophagoscope, aspirating tube and mass out together. The esophagoscope was reinserted and the esophagus was found to be clear, no apparent damage had been done. About two thirds of a pint (330 cc.) of gelatinous material was recovered with the plug.

It has now been seven months since this occurred and the patient has experienced no esophageal symptoms of any kind, outside of constipation, which is not now being treated with Saraka; she has been in good health.

The condition was due to haste in carrying out the directions given, but it emphasizes the danger in administering a hygroscopic gum laxative and the necessity for exact instructions and the importance of rigidly following these instructions.

According to the report of the Council on Pharmacy and Chemistry of the American Medical Association, Saraka owes its activity to the elements—an indigestible gum called bassorin, which has the power to absorb water and increase greatly in bulk and the drug frangula, which is much like cascara.

**Special Clinical Article****THE RATIONAL CONSIDERATION OF  
PERIPHERAL VASCULAR DISEASE**

BASED ON PHYSIOLOGIC PRINCIPLES

CLINICAL LECTURE AT SAN FRANCISCO  
SESSION

ALTON OCHSNER, M.D.

AND

MICHAEL DeBAKEY, M.D.

NEW ORLEANS

The rapid strides that have characterized the developments in the treatment of peripheral vascular disease during the past decade have been due in the main to a more rational comprehension of the disease process. Whereas previously studies were based on the apparent anatomic-pathologic changes, the recent concept emphasizes the less obvious alterations in physiologic function. The recognition of the associated fundamental physiologic derangement has permitted an approach toward accuracy in prognosis and efficacy in therapeutics.

Peripheral vascular disease signifies simply a disturbance or actual diminution in the normal amount of circulating blood to a part. This is usually due to a decrease in the intraluminal volume of the peripheral vessels and may be caused by two factors operating either singly or together depending on the type and stage of disease: (1) obliterative structural change in the vessels and (2) abnormal vessel spasticity. Whereas the former is an unalterable pathologic lesion, the latter represents a physiologic or functional disorder which can be satisfactorily influenced by appropriate therapy. Thus it is obvious that a rational consideration of peripheral vascular disease is possible only from a pathologic-physiologic standpoint which forms the basis of the following classification: (1) vasospastic functional disease, (2) vasospastic organic disease, and (3) organic degenerative disease. The presence or absence of vessel spasticity obviously forms the basis of this classification and its decisive importance is clearly understood when one realizes that it is the one controllable factor and therefore of prognostic and therapeutic significance. Since the degree of vasospasm varies in each case, it is necessary to determine not only its presence or absence but also its extent. Thus it becomes increasingly important that some simple and accurate diagnostic means or methods be developed for such determinations.

Although a detailed survey of the various procedures designed during the past decade by investigators all over the world for studying vasospasm is beyond the scope of this presentation, it is considered desirable to review them briefly. Since vasospasm is a physiologic function of the autonomic nervous system, the fundamental principle of most of these procedures is the same and allows them to be classified on this basis into two groups: (1) temporary interruption of impulses over the sympathetic pathways by anesthesia and (2) the use of some physiologic stimulus to produce transient inhibition of sympathetic tone. A detailed classification is given in table 1. After the vasospastic influences are removed or diminished by one of the methods listed,

the effect on the peripheral blood supply is determined by the objective methods shown in table 2.

It has long been a well established fact that interruption of impulses in a peripheral nerve results in increased temperature of the cutaneous areas supplied by that nerve.<sup>1</sup> Conduction block of the peripheral nerve by infiltration with procaine hydrochloride has been used as a diagnostic procedure in determining the vasospastic influence in peripheral vascular disease. Lewis,<sup>2</sup> White,<sup>3</sup> Morton and Scott<sup>4</sup> and de Takats.<sup>5</sup> The injection into the peripheral nerve of procaine hydrochloride is indicated in relatively few cases because of technical difficulties and because of trauma to the nerve itself and the surrounding tissue which in persons with a basal blood supply is a potential danger. We have observed several cases in which this diagnostic procedure was used with consequent tissue necrosis, ulceration, secondary infection and eventual gangrene of the extremity requiring amputation.

The injection of an analgesic agent into the subarachnoid space also can be used to produce interruption of sympathetic impulses to the lower extremity. Spinal analgesia for this purpose has been recommended by Brill and Lawrence,<sup>6</sup> Morton and Scott,<sup>7</sup> and White.<sup>8</sup> While it may be justified during an operative procedure, its use is not warranted as a routine diagnostic test in cases of peripheral vascular disease because of its potential dangers and because it interrupts all the regional pain impulses, with consequent difficulty in evaluating the significance of the vascular occlusion.

As the vasospastic impulses are conducted over the sympathetic nervous system, the ideal procedure for determining the degree of vasospasm would be one which completely interrupted only these impulses to the involved area. Such a procedure can be performed with relative facility and safety by a procaine hydrochloride block of the ganglions where the pathways over which these impulses travel converge. Leriche<sup>9</sup> in 1927 was the first to advocate this as a diagnostic procedure in determining the extent of vasodilatation in peripheral vascular disease and it has since been popularized by White,<sup>8</sup> Flothow,<sup>10</sup> de Takats,<sup>5</sup> and us.<sup>11</sup>

- 18 Ochsner Alton and DeBakey Michael. Diagnostic Significance of Novocain Block of the Cervicodorsal Sympathetic Ganglions. Description of a New Technique to be published.

From the Department of Surgery, Tulane University of Louisiana School of Medicine.

Read in the Surgical Division of the General Scientific Meetings at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 14, 1933.

In the lower extremity this block is accomplished by the injection of the second, third and fourth lumbar ganglions on the affected side with procaine hydrochloride by the Labat<sup>12</sup> or the Kappis<sup>13</sup> technic. Although the posterior approach also may be employed for the upper extremity<sup>14</sup> the anterior approach, i.e. injection of the stellate ganglion directly,<sup>11</sup> is preferable in our opinion because of its greater facility.

General anesthesia has long been known to exert a vasodilatory effect.<sup>15</sup> Because of this, Morison and Scott<sup>4</sup> suggested general anesthesia as a diagnostic method of demonstrating the presence or absence of vasospasm. However, general anesthesia is undoubtedly not justified as a routine diagnostic measure because of the discomfort which it causes the patient, because of the added risk of the anesthesia itself and because it obviously does not produce complete generalized vasodilatation. Probably the only cases in which general anesthesia is justified as a diagnostic procedure in determining the degree of vasospasm are, as suggested by White,<sup>16</sup> those in which there is an obvious vasospastic functional disease for which an operative procedure is indicated. After the induction of the anesthesia but before the operation is performed, the degree of vasodilatation can be determined relatively quickly, and the anesthesia need be prolonged very little.

A number of other methods can be employed to relieve vasospastic influences. These probably produce an inhibition of the sympathetic impulses to the peripheral vessels resulting in their decreased vascular tone. The artificial induction of fever following injection of foreign protein was used first by Brown<sup>17</sup> in 1926 and

Although Brown deserves considerable credit for calling attention to the necessity of determining the degree of vasospasm, injection of foreign protein as a routine diagnostic procedure is considered undesirable because of the severe reaction, the extreme discomfort experienced by the patient and the fact that complete generalized vasodilatation is obviously not produced.

The fact that a slight increase (from 0.01 to 0.04 degree C) in the temperature of the blood, as shown by Pickering,<sup>20</sup> produces vasodilatation in the skin through the action of the central heat-regulating mechanism has led to the development of several simple tests for determining the degree of vasospasm. Lewis and Pickering<sup>21</sup> first utilized this fundamental principle for such a purpose by placing the patient's body in a cabinet heated by electric light bulbs. A somewhat similar procedure has been recommended by Collier and Maddock<sup>22</sup> and consists of wrapping the patient up to the clavicular line in three woolen blankets and a rubber sheet. Landis and Gibbons<sup>23</sup> have developed an even simpler test in which the uninvolved arms or legs are immersed in warm water (45 C for thirty-five minutes) while the extremities to be tested are not exposed to heat. The chief disadvantages of these methods are the discomfort caused the patient, the fact that complete generalized vasodilatation undoubtedly cannot be produced and the fact that a room with constant temperature and controlled humidity is required. However, the application of heat to a relatively small portion of the body, as in the immersion of the legs in warm water when the upper extremities are involved, is a relatively simpler and more generally applicable method. The procedure recently proposed by Reynolds<sup>24</sup> of determining the ability of the peripheral arterial system to dilate and to carry off heat applied to it by diathermy cannot be considered justifiable. The disadvantage and even danger of such a method lies in the fact that, everything else being equal, the poorer the blood supply to an extremity the higher will the temperature of the part become because of the diminished vascularity and the consequent inability of the circulating blood to carry off the increased heat. The fact, too, that the subjective changes experienced by the

patient form the criterion of the test makes it less accurate than the more objective methods

Bier<sup>25</sup> and Moskowitz<sup>26</sup> made the original observations that immediately after the release of circulation to a part, when the circulation has previously been arrested for a few moments, there appears a bright flush (reactive hyperemia), which rapidly spreads distally. The intensive studies of Lewis and Grant<sup>27</sup> led them to believe that this phenomenon is due mainly

are theobromine,<sup>31</sup> acetyl  $\beta$ -methylcholine<sup>32</sup> and sodium nitrite<sup>33</sup>. While such drugs have the advantage of being easily administered, with little or no discomfort to the patient, a distinct disadvantage of their use is that the effect is generalized, which is unnecessary, and since it is generalized it obviously cannot be complete without a marked fall in blood pressure.

The extent of vasodilatation resulting from release of vasospastic influence by the various procedures

Fig. 1—Oscillometric graphs of a patient with vasospastic organic disease of the lower extremities. A before sympathetic block the oscillometric index is approximately 1.75. B twenty minutes after procaine hydrochloride block of the right lumbar sympathetic the considerable increase in pulse volume demonstrated by an increase in the oscillometric index from 1.75 to 5.25 clearly reveals the presence of vasospasm.

to the accumulation of chemical substances in the tissues during the period of circulatory arrest. These fundamental principles form the basis for the development of the reactive hyperemia tests as used and advocated by Lewis, Pickering and Rothschild<sup>28</sup> in the determination of vasomotor tone. The test is performed in a room with a temperature of 20 C or over with the subject comfortably warm. The extremity to be tested is elevated and the circulation abruptly arrested by inflating above systolic pressure a sphygmomanometer cuff applied to the arm or thigh. After the extremity is lowered to the horizontal position and five minutes is permitted to elapse, the pressure is released. The course of the flush is observed. In normal subjects and patients with pure vasospastic functional conditions the flush reaches the tip of the digits within five to fifteen seconds and rapidly disappears. However, in patients with organic change in the vessels the flush spreads slowly, occasionally requiring a minute or more, usually has a cyanotic hue and frequently lasts for a longer period.

Certain drugs are known to have a vasodilatory action and therefore have been used diagnostically as well as therapeutically. The vasodilatory effect of alcohol has been repeatedly observed,<sup>29</sup> and the optimum dose for maximum vasodilatation has been estimated to be 0.5 cc per kilogram of body weight.<sup>30</sup> Other drugs that have been found to produce this effect

obtained by means of either a mercury thermometer or a thermocouple, but the latter is by far the more accurate. However, it is necessary that these observations be made in a room with constant temperature and controlled humidity.

The determination of peripheral pulsations is of diagnostic importance in cases of peripheral vascular disease because diminution in pulsation may be due to decrease in intraluminal volume consequent to either organic occlusion or vasospasm. The extent of vascular expansive pulsations can be determined by oscillometric or plethysmographic methods. Pulsations in larger vessels can be determined either by the Pachon method or by the recording oscillogram. The disadvantage is that determinations so obtained represent

Fig. 2—Oscillometric graphs of a patient with vasospastic functional disease of the upper extremities. A before sympathetic block the oscillometric index approximately 5.5 is apparently normal. B twenty minutes after procaine hydrochloride block of the right cervicothoracic sympathetic the oscillometric index is practically the same as before the block. However the acceptance of these observations as indicating absence of vasospastic influence would be misleading as is clearly demonstrated by figure 3.

pulsations of the large vessels in the main and are of little or no value when the disease is more peripheral. On the other hand, pulsations of the smaller vessels can

be accurately determined and graphically recorded by means of plethysmographic methods

For the past eight years we have used oscillometricograms in the diagnosis of peripheral arterial disease and have observed that they are of value when the larger vessels are involved but are of little or no diagnostic value when the involvement is more peripheral. This is well illustrated by two of our cases. In one, of vasospastic organic disease, the oscillometric index of the lower extremities was definitely decreased (fig 1 A). After procaine hydrochloride sympathetic block the increased oscillometric index revealed marked vasospasm (fig 1 B). In a case of vasospastic functional disease involving the upper extremity oscillometricograms both before and after injection of procaine hydrochloride into stellate ganglions were normal (fig 2). On the other hand, plethysmographic tracings of the distal phalanges revealed absence of pulsations prior to the procaine hydrochloride sympathetic block (fig 3 A). However, the presence of normal pulsations after the block demonstrated that this was simple, marked arteriolar vasospasm (fig 3 B). Therefore the method employed should depend on the type of lesion suspected, i. e. on whether the lesion involves the larger arteries or the smaller vessels. While oscillometry is of diagnostic value in the former case, plethysmography should be employed when the smaller vessels are involved. Because in the purely vasospastic functional diseases the spasm apparently involves the smaller vessels, particularly those in the fingers, and in the early stages is frequently limited to these small vessels, the ordinary plethysmograph may not record the changes sufficiently accurately. For this reason a very sensitive plethysmograph is necessary. In that respect we have been particularly fortunate in having the cooperation of Dr Turner and his co-workers Drs Sodeman and Buch in studying our cases. With the ingenious and highly sensitive plethysmograph devised by Turner<sup>34</sup> it is possible to measure accurately and record either quick changes in pulse volume as small as 0.1 cu cm or slower changes of relatively greater magnitude, i. e. up to 800 cu mm. Moreover, there is no influence of instrumental origin, such as mechanical pressure, causing constriction and consequent distention or emptying of blood vessels or the production of pain, fear or other discomforts which may modify the physiologic phenomena. Because the portion of the extremity included in this plethysmogram is the phalanx, the apparatus is particularly applicable to the study of changes of volume in the very small vessels (fig 3). Thus it has been possible to make highly accurate determinations of the presence or absence and the degree of vasospasm in small vessels which could not be recorded by previous inadequate and insufficiently sensitive methods. The method of study lends itself as well to the determination of the degree of venous tone which is particularly evident with acrocyanosis.<sup>35</sup>

Visualization of the vascular tree either directly by microscopic examination of capillaries or indirectly by arteriograms will give graphic demonstrations of the status of large and small vessels. The former method was introduced by Lombard<sup>36</sup> in 1912 and has since

been used by a number of investigators.<sup>37</sup> By direct observation it is possible to determine the number and size of capillary loops, the relative rate of blood flow through them signifying the degree of vasospasm or dilatation. However, the application of direct observation as a routine clinical method is somewhat limited because of technical difficulties and the considerable relative variability in individual interpretation.

Roentgenograms taken during and immediately after the intra-arterial injection of an opaque substance indirectly reveal the presence or absence of vasospasm. The Portuguese school, headed by dos Santos and his co-workers,<sup>38</sup> probably has made the most extensive use of such roentgenograms. In this country they were originally made by Pearse and Warren<sup>39</sup> and have been used most intensively by Allen and Camp<sup>40</sup> and Veal.<sup>41</sup> Although they are of undeniable value in the accurate determination of the extent and location of

Fig 3—Plethysmographic tracings of the distal phalanx of the patient represented in figure 2. A prior to sympathetic block, pulsations are practically absent. B twenty minutes after procaine hydrochloride block of the cervicodorsal sympathetics the pulsations are now practically normal indicating the marked vasospasm present in the smaller vessels.

spastic functional disease is not great. Moreover, the contrast substances most commonly used iodide compounds and thorium dioxide, for the intra-arterial injection have certain distinct disadvantages. The former is frequently associated with so much pain that the injection must be performed with the aid of an anesthetic, in some instances it probably produces vasospasm which undoubtedly increases damage to vessels, thus diminishing the already impaired circulation. Thorium dioxide is radioactive and becomes indefinitely fixed in the tissues. Several years ago the Council on Pharmacy and Chemistry directed attention to the possible deleterious effect of such radioactive substances.<sup>42</sup> Since then the results obtained in numerous clinical and experimental investigations have emphasized the proclivity of this material to produce damage to tissue.<sup>43</sup>

In addition to these objective methods of determining the presence or absence and the extent of vasospasm there are certain clinical factors which indicate and in some instances influence vessel spasticity (table 3).

It is a well known fact that other things being equal the younger the patient with peripheral vascular disease the greater is the likelihood of vasospasms playing a prominent part. The condition is usually of the vaso-

degenerative type, their total absence being observed more frequently with vasospastic lesions. However, the recent investigations of Reich<sup>44</sup> which clearly demonstrate that pulsation may be absent from one or more of the main vessels of the foot in persons with perfectly normal peripheral circulation, stress the necessity of not placing too much emphasis on such observations in the absence of other evidence of peripheral vascular disease.

Hyperhidrosis, or excessive sweating, is characteristically associated with vasospastic diseases and is an indication of hypertonus of the sympathetic nervous system.<sup>45</sup> It is usually a prominent manifestation of vasospastic functional disease but is rarely observed with degenerative organic conditions.

The most influential factors in vasospastic conditions are emotional excitement, exposure to cold and tobacco smoking. While emotional disturbances are particularly likely to aggravate and even precipitate vasospasm in patients with vasospastic functional disease, they are relatively insignificant in patients with organic lesions. Similarly, exposure to cold is a considerably more important precipitating factor in vasospastic functional conditions, although all peripheral vascular diseases are aggravated by decreases in temperature.

It has long been a well established fact that tobacco smoking produces definite deleterious effects on the vascular system.<sup>46</sup> Numerous investigators have clearly demonstrated that it produces marked vasoconstriction of the peripheral vessels in normal persons as well as in patients with peripheral vascular disturbances.<sup>47</sup> While it is especially harmful to patients with vasospastic functional and vasospastic organic lesions, it probably produces a deleterious effect on patients with degenerative organic disease by affecting the collateral vessels.

As previously stated, peripheral vascular disease merely signifies a disturbance in the normal amount of circulating blood, which in turn is dependent on two factors either or both of which may be present: (1) obliterative structural change and (2) abnormal spasticity. The former is an unalterable pathologic lesion and therefore cannot be effectively influenced by

TABLE 3—Clinical Factors Indicating and Influencing Spasticity

spastic functional type in persons less than 30 but of the degenerative organic variety in patients past 50. This applies particularly to females with regard to the former group. Between these two extremes of age are persons in whom organic occlusion is associated with considerable vasospasm. Men are much more prominent in this middle age group. The conditions most typical of the three groups are Raynaud's phenomenon in the first, arteriosclerosis with or without diabetes in the second and thrombo-angitis obliterans in the third.

Certain color changes may indicate the presence or absence of vasospasm, particularly with regard to various positions of the extremity. In vasospastic functional disease the typical triphasic color changes are likely to occur independently of position. In vasospastic organic disease the skin of the extremity presents a prominent paleness in the elevated position and a violaceous discoloration in the dependent position, and in degenerative organic disease the conspicuous cutaneous pallor changes little or not at all in different positions.

The presence or absence of peripheral pulsations is also of undeniable significance. In the purely vasospastic functional disturbances these pulsations are usually perfectly normal. On the other hand, they are most commonly diminished or absent in patients with organic lesions of either the vasospastic or

therapeutic measures, the latter is a physiologic or functional derangement and can be satisfactorily controlled by appropriate therapy. Since vasospasm is the one controllable factor it becomes increasingly obvious that its release must form the basis of efficacious therapy. Thus rational treatment of vascular disease of the extremity consists of (1) the avoidance of those factors which increase vessel spasticity and (2) the institution of measures which produce vasodilatation.

As previously emphasized, the three most important vascular spasmogenic factors are emotional disturbances, exposure to cold and tobacco smoking. These factors are harmful in all cases of peripheral circulatory disturbances, but they are particularly injurious in cases of vasospastic functional or vasospastic organic disease. Obviously, every attempt should be made to avoid emotional excitement such as anxiety, fear and anger. When possible the patient should live in a warm climate, and under any circumstances he should have all the surface of the body protected during cold weather because exposure of one portion of the body is likely to produce a reflex vasoconstriction in other parts. Thus patients with vascular disturbances involving primarily the lower extremities should be careful to protect the upper as well as the lower extremities and during cold weather should wear warm mittens as well as warm socks.

As emphasized, tobacco smoking produces marked vasoconstriction of the peripheral vessels. This process by further diminishing an already impaired peripheral circulation is obviously injurious. Thus in all cases of peripheral vascular disease tobacco smoking must be absolutely prohibited. We have repeatedly observed its spasmogenic significance and it is our firm conviction that of all the precipitating factors it is by far the most important.

In addition to the avoidance of precipitating factors, effective therapy consists in the institution of active vasodilatory measures. These may be classified as (1) conservative and (2) radical. The conservative measures include the administration of vasodilatory drugs, the application of heat, vascular exercises and the induction of reactive hyperemia.

In our experience alcohol is one of the most valuable vasodilatory drugs, as it is simple to administer and readily obtainable. The patient is usually advised to take one or two highballs. In many instances alcohol imbibition and the application of heat as outlined hereafter are sufficient to prevent a vascular catastrophe. Other vasodilatory drugs which have been employed are acetyl- $\beta$ -methylcholine,<sup>48</sup> theobromine<sup>51</sup> and paverine hydrochloride.<sup>49</sup>

The proper application of heat to the body is one of the simplest and yet one of the most efficacious vasodilatory measures. As emphasized, because of the danger of injuring an extremity in which the circulation is diminished, it is desirable not to apply the heat directly to the involved extremity. It has been demonstrated by Lewis and Pickering<sup>50</sup> and emphasized by Gibbon and Landis<sup>23</sup> that the application of heat to a localized portion of the body induces generalized vasodilatation. Thus the patient with a vascular disturbance involving the lower extremity is instructed to immerse the hands and forearms in warm water for from twenty to thirty minutes three or four times daily.

Other conservative measures which have been advocated and may be helpful in the treatment of vasospastic organic lesions are postural exercises as described by Buerger<sup>46</sup> and intermittent venous occlusion.<sup>51</sup> In cases of degenerative organic lesions, passive vascular exercises may also be valuable.<sup>52</sup>

In the presence of marked and progressive vasospasm which is not relieved by conservative measures it may be justifiable to resort to more radical procedures. The concept that in such vasospasm sufficient vasoconstrictor impulses are transmitted over the sympathetic pathways to cause diminished circulation and that the interruption of these impulses may be enough to permit the return of circulation to normal forms the rational basis of sympathectomy.<sup>53</sup> This interruption may be accomplished either by chemical block or by resection. Chemical block may be obtained by the injection of the appropriate paravertebral ganglion with procaine hydrochloride or alcohol. The obvious disadvantage of procaine hydrochloride is the short duration of the block. A satisfactory alcohol block may be secured for a period of from six to eight months but it is not infrequently associated with undesirable sequelae. This applies particularly to the cervicodorsal region, where the proximity of the brachial plexus so increases the likelihood of neuritis of the brachial plexus that the procedure is not justifiable. For this reason sympathetic denervation of the affected part by a surgical procedure, unless there is some definite contraindication to operation, is considered preferable.

While the immediate effect of sympathectomy on vasospastic disease both of the upper and of the lower extremities is almost invariably excellent, it has been observed that the end results in the lower extremities are considerably better than those in the upper.<sup>54</sup> The comparative failure of cervicothoracic sympathectomy to maintain chronic vasodilatation has been attributed to a number of factors. However, the most satisfactory explanation has recently been indicated by White, Freeman and Smithwick<sup>55</sup> and by Ascroft,<sup>56</sup> who directed attention to the significant fact that, after the customary procedure of cervicothoracic ganglionectomy for the upper extremity, degeneration of the postganglionic

neurons occurred with resultant hypersensitization of the denervated vessels to the circulating hormone epinephrine. On the other hand, the conventional lumbar sympathetic ganglionectomy is actually a preganglionic neurectomy permitting the postganglionic fibers to the vessels of the foot to remain intact, thus avoiding degeneration and consequent hypersensitization. These statements are based on the original observations of Elliott<sup>57</sup> and the more recent investigations of Rosenbluth and Cannon,<sup>58</sup> Grant,<sup>59</sup> Hampel,<sup>60</sup> and White, Okelberry, and Whitelaw,<sup>61</sup> who demonstrated by animal experimentation that smooth muscles innervated by the sympathetic nervous system become hypersensitive to epinephrine after denervation.

Basing their work on these investigations Smithwick<sup>62</sup> and Telford<sup>63</sup> recently described and advocated a technic for cervicodorsal sympathectomy in which the preganglionic fibers are sectioned and the postganglionic fibers are left intact. However in both procedures the white communicating ramus of the first thoracic nerve is allowed to remain intact on the assumption that preganglionic components of the first thoracic nerve have no significant function in the sympathetic innervation of the upper extremity. On the basis of their recent experimental observations Kuntz, Alexander and Furcolo<sup>64</sup> took exception to this supposition and concluded that in order to produce complete functional sympathetic denervation it is necessary also to interrupt the white communicating ramus of the first thoracic nerve.

It has been affirmed repeatedly that peripheral vasoconstriction can be initiated by reflex activity of the autonomic nervous system and by an increased secretion of epinephrine. The stimuli cold and emotional excitement produce vascular spasm by reflex excitation of vasoconstrictor impulses to blood vessels and by reflexly increasing the secretion of epinephrine. Thus the mechanism of peripheral vasoconstriction under such circumstances may be humeral as well as neurogenic. The surgical procedures indicated represent an attempt to diminish the neurogenic activity. However, the part played by the humeral factor in vasospastic functional and vasospastic organic conditions may be important. In an attempt to decrease also the reflex activity of this humeral factor, Leriche, Pereira and DeBakey<sup>65</sup> recently advocated simultaneous resection of the splanchnic nerves and the first and second lumbar

sympathetic ganglions. In cases of vasospastic functional and vasospastic organic peripheral vascular disease of the lower extremities in which lumbar sympathectomy is indicated, the additional performance of splanchnic section can be readily accomplished with little or no technical difficulty through a new extra peritoneal approach which they describe.

### SECOND ANNUAL SUMMARY OF FOURTH OF JULY INJURIES

DUE TO FIREWORKS AND EXPLOSIVES

#### SECOND SERIES

In 1937 the American Medical Association resumed its annual summaries of injuries resulting from the celebration of the Fourth of July with fireworks.<sup>1</sup> As pointed out in that report, the considerable increase in the number of such injuries made it expedient to renew the annual reviews.

#### DEATHS

In 1938 there were eighteen deaths reported as directly due to the celebration of the Fourth of July with fireworks and other explosives and seven addi-

tional deaths indirectly due to the same cause. The distribution by states is given in table 1. It may be noted that in 1938 Pennsylvania led all other states with six deaths from fireworks and two additional deaths attributable indirectly to this cause.

There were two main causes of death—the body burns suffered by little girls when their flimsy dresses caught on fire from sparklers or firecrackers, and the mutilations received by boys or men as the result of their experiments with home-made explosives. The first of these causes took the lives of eight little girls, three of them in South Bend, Ind. The stuffing of lead pipes with firecrackers and similar ventures resulted in death for five boys and men. One such accident cost an 11 year old boy his life, while a companion had his

left leg and fingers blown off and another lost the toes of his left foot. Another experiment caused a man to have both hands blown off with subsequent loss of life and his brother to lose one eye and suffer other injuries. Among the other deaths were those of a young man employed in a fireworks factory in Ohio, who died of burns when he was trapped in a room with exploding fireworks, and of a 2½ year old girl when a torpedo under a can shot the jagged tin against her, resulting in evisceration of her stomach, intestine, omentum and liver.

Three of the seven deaths reported as due indirectly to the Fourth of July celebration resulted from the careless use of firearms. In another accident a 4 year old boy, frightened by a lighted firecracker which he had picked up, jumped from a porch and landed on a stick. He died later from intra-abdominal perforation. An elderly woman fractured her hip when she fell to the sidewalk, frightened by a firecracker, she died of pneumonia which developed as a result of this accident. While attempting to escape the explosion of a firecracker he had just lighted, a Baltimore youngster ran into an automobile and died from resultant injuries.

TETANUS

In 1938, as in 1937, only two cases of tetanus were reported—one in New York and the other in Pennsylvania. The New York patient had a gunshot wound in the palm from a blank cartridge. No antitetanic serum was given and eighteen days later he developed spasm of the muscles of mastication. Tetanus bacilli were isolated from the wound by culture. In the succeeding seven days he received 1,075,500 units of antitoxin. He recovered completely and was discharged from the hospital after forty-eight days.

The Pennsylvania patient was injured by a torpedo which struck a limb of a tree and exploded close to him, causing a puncture wound in the area of Scarpa's triangle. He was treated for the resulting hemorrhage and given 1,500 units of tetanus antitoxin. Eight days later symptoms of tetanus began to appear. He was given 40,000 units of tetanus antitoxin intraspinally, 40,000 units intramuscularly and 10,000 units intravenously, after which the symptoms of tetanus subsided and the tetanus was considered to be controlled. He died shortly after from secondary hemorrhage.

SERIOUS INJURIES

Newspaper clippings and hospital questionnaires recorded a number of serious or extraordinary injuries resulting from fireworks. Nearly three times as many persons lost the sight of one or both eyes as in 1937, while there were over twice as many amputations as in that year. A woman was hit in the eye with a rocket, jumped back, fell and sustained a fracture to the spine. A man in Michigan had some fingers blown off by an aerial bomb, amputation of his left arm was later required. A 6 year old girl was burned so severely that she required extensive skin grafts and was still hospitalized three and a half months after the injury. Similar injuries requiring extended hospitalization were recorded in 1938 with great frequency.

INJURIES

In table 2 are listed the injuries recorded from fireworks in 1938 and in a parallel column the injuries for 1937. In 1938 the total number of injuries recorded

was 7,933 as compared with 7,205 in the preceding year. Since these figures do not take into consideration the injuries treated in hospitals which failed to report or those treated by physicians in their offices, they obviously err on the side of underestimation.

New Jersey, with a state law banning fireworks, again has a low record of injuries from fireworks,

although the slight rise from the previous year may be interpreted as indicating the necessity for continued efforts at enforcement. Michigan, Kentucky and Wisconsin also exhibited evidence of reasonably effective legislation. Some of the other states appear to show what amounts to a serious increase in the number of injuries from a level already much too high.

Pennsylvania, besides contributing one third of the deaths, has also the doubtful honor of recording the highest total number of injuries and is second only to Rhode Island in the ratio of injured to the total

population. Furthermore there were twice as many amputations in Pennsylvania as in any other state. Other states with notoriously bad records were Indiana, New York, California, Massachusetts, Connecticut, Illinois, Minnesota, Missouri and Ohio. A few states, however, have shown a definite reduction of accidents from the previous year. Of these Iowa, which in

TABLE 3—Recapitulation of Total Injuries by Type

Injuries	1935	1937
Burns and lacerations	718	1,535
Loss of vision of one or both eyes	41	16
Injury to eye	251	291
Loss of finger, hand or other member	80	57
Internal injury, fracture or other serious accident	71	Not classified
Total injuries	793	7,201

1937 recorded seventy-six injuries, had in 1938 only six, this improvement being obviously attributable to antifireworks legislation enacted in the interim. Idaho, Kentucky, Nebraska, Oklahoma, Oregon, Vermont, Washington and the District of Columbia also showed some improvement over the preceding year. Michigan, which has possessed a state law for several years, showed evidence of good enforcement by a further reduction of recorded injuries from 190 to 107, which while still too high, is much better than the records of such neighboring states as Indiana and Illinois without state laws.

Although displays by competent operators are to be preferred to individual celebration with fireworks, injuries due to such displays have by no means been eliminated. A display at Portage Park in Chicago resulted in the injury of at least seventeen persons, three children and a woman requiring hospitalization. In a similar accident at Rock Island Ill. a man and his wife were so severely burned on the legs, hands and abdomen that they required hospitalization for several days, while seven others received minor injuries. In Mississippi a Negro hired to engage in a six boat roman candle fight for the amusement of others was drowned when forced to jump overboard to escape being burned.

TABLE 4—Injuries in Principal Cities

City	1935		1937	
	Injuries	Rate per 100,000	Injuries	Rate per 100,000
St. Louis	295	15.88	372	9.17
Philadelphia	418	21.22	201	10.30
Los Angeles	380	14.9	45	3.63
New York	1,008	14.43	324	7.56
Cleveland	123	14.2	64	7.11

Chicago	176	21	227	6.66
Detroit*	27	1.39	62	3.95

\* Of thirty cards of inquiry sent to Detroit hospital only four were returned.

The Southern group of states again reported few injuries from fireworks. This appears to be due, as pointed out last year, to the fact that in most regions of the South there is no fireworks celebration on the Fourth of July. In the South the Christmas season is usually celebrated with fireworks, and the accident toll at that time is in some states not inconsiderable.

Many large cities in states without antifireworks laws possess ordinances against the sale and in some

instances against the use of fireworks within their corporate limits. Nevertheless in 1938 as in 1937 most of the large cities recorded numerous injuries, many of them serious (table 4). St. Louis again led all other cities in the ratio of injuries to the population. Philadelphia, Los Angeles, New York and Cleveland showed large increases not only in the total number of injuries recorded but in the rate of injuries per hundred thousand of population. In these four cities and St. Louis alone there were 2,030 injuries as compared with only 1,156 in 1937. Again it is obvious that local regulations are only partly effective in preventing fireworks injuries in big cities since, without state laws forbidding fireworks can easily be purchased outside the city limits and brought in by automobile.

## COMMENT

More striking than ever is the evidence in 1938 that many regions are woefully lacking in adequate legislation for the prevention of injuries and fatalities from fireworks. Numerous states and cities have shown serious increases in recorded accidents. In general only those states which have enacted and enforced statewide laws have shown any evidence of satisfactory control. Some of the states with antifireworks legislation have failed to realize the benefits which might have been expected because of the lack of such legislation in neighboring territories and the ease of transportation. With the high incidence of injuries from fireworks continuing unabated in spite of the knowledge of how to overcome this danger, there is no longer any excuse for failure to adopt effectual state legislation.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT H. A. CARTER, Secretary

## NOMIS PURE AIRE UNIT (OZONE GENERATOR) NOT ACCEPTABLE

Manufacturer: The Nomis Corporation, Lafayette, Ind.

At times, in order to fulfil its assumed obligations to the medical profession and to the public, the Council may consider itself called on to investigate and prepare reports on devices which have not been submitted, if such reports, in the opinion of the Council, are important to public health and welfare.

The Nomis Pure Aire is advertised as coming in two sizes. The smaller unit was purchased on the open market and investigated. This "Standard Model" weighs approximately 6 pounds while a larger one weighs a few ounces more. According to the information in the advertising of the firm the smaller unit produces 0.075 Gm. of ozone per hour, while the six plate or larger model produces 0.225 Gm. per hour.

Equipment includes a transformer and small electric motor with fan and four plates. Each plate consists of a flat conductor embedded in an insulator about  $4\frac{1}{4}$  inches long and  $1\frac{3}{4}$  inches wide. When it is suitably connected to the high tension leads of the transformer and the primary current is turned on, a corona is produced between the plates. There did not appear to be a true electric spark. Ultraviolet rays present in the corona appear to be the principal agent creating ozone. The investigator reported that the machine was cheaply and poorly constructed. However, it is believed that the unit complied with standard requirements concerning safety and fire risk. It is operated on 110 volts alternating current and draws 25 watts. The electromotive force on open circuit across the condenser lead wires is about 50,000 volts. The high voltage wires are protected.

A similar device may be made by connecting the high tension leads of a step-up transformer to a condenser made in the following manner. Four metal strips are separated from each other by alternate glass insulators. Two strips are connected in parallel at one end and in turn connected to one lead from the transformer, and the other two remaining strips connected to the other lead, thus making a metal and glass condenser. With an alternating current passing through the primary transformer, an alternating high tension current is induced in the secondary, and a corona is observed within the laminated structure.

The Nomis Pure Aire unit and the home-made one were examined in a laboratory acceptable to the Council.

A spectrogram of the corona formed between the fiber strips was made with a Bausch and Lomb medium quartz spectrograph, using a slit width of 1 mm and slit length of 22 mm with an exposure of eleven hours in a dark room. Spectrogram A consisted of a series of eight bands with the maxima at approximately 2,810, 2,960, 3,140, 3,360, 3,550, 3,770, 4,000 and 4,270 angstrom units. These bands probably consisted of a series of lines but, owing to the width of the slit, appeared as bands on the plate.

Another spectrogram was made using as a source the corona made by the home made condenser consisting of four metal strips separated by alternate glass insulators. Spectrogram B shows bands at the same wavelength as those shown by the unit under consideration. The time of exposure was seven hours.

In addition, the apparatus was investigated and the advertising reviewed by a reliable physiologist. He stated that the fact that the Nomis machine does produce ozone is not to be disputed. The therapeutic and physical claims which the company makes for its unit as an ozone producing device are the points under question. For example, the statement that the current comes in contact with no metal<sup>1</sup> is absurd because it is common knowledge that electric current is largely generated with the aid of metal, carried to a machine by metal and distributed throughout a machine by metal.

The statement 'the Nomis is scientifically gauged so as to furnish only the proper amount of exhilarating ozone' is patently inaccurate, since only an on and off switch is provided to control the amount of ozone no matter how large or how small the room.

A further statement, 'turned on continuously it would not create an undesirable excess of ozone in the atmosphere of the room in which it is installed even if run all day,' is equally misleading, since the assumption is made that this would apply not only to a tiny dressing room but also to a large living room.

According to one claim in the pamphlet 'Pure Air,' 'the primary purpose of the Nomis is destruction of fumes, gases, odors and germs and thus the creation of proper air for the lungs and skin and blood stream of healthy people. This promotes health and efficiency. Throughout the pamphlet there are recorded statements such as 'kills poisonous gases, destroys fumes, kills germs, destroys odors' 'in 10 to 15 minutes the germs and poisonous gases have been oxidized—burnt up' 'the lurking germs that cause colds and more serious ailments killed by ozone,' 'it literally burns up disease germs and bacteria,' 'this form of oxygen, so rich in tonic for the human body and so deadly to fumes, odors, and germs, is called ozone' 'the Nomis 'Pure Aire' instrument supplies ozone to burn up 1 c to destroy the poisonous gases, odors, fumes, and germs that are created or entrapped inside of every four walls'.

An analysis of these statements apparently indicates that the Nomis Corporation claims for its machine at least two major points: that (1) ozone destroys disease germs and bacteria, and (2) ozone destroys poisonous gases, odors and fumes.

With regard to the first of these claims, long ago qualified investigators showed that ozone had little or even no effect on germs and bacteria let alone "literally burning them up."<sup>1</sup> These experiments were performed on all kinds and types of

bacteria (germs) in both the dry and the moist condition. Ozone to be even a little effective had to be present in such concentrations as were shown to be distinctly harmful to the delicate membranes of the nose, throat and lungs of a human being. Modern work has verified these observations,<sup>2</sup> whereas the Nomis Corporation has presented no critical evidence to support the claims in its advertising matter.

As for the second of these claims, critical investigators have shown that the action of ozone as a deodorant is merely that of a masking agent—in other words merely a substitute.<sup>3</sup> Investigations show that, when the ozone is dissipated, the odors, fumes and "poisonous gases" remain practically unaffected. The reason for this is twofold: (1) Ozone has been shown to be quite ineffective as an oxidizer for fumes, odors or gases, and (2) ozone tends to fatigue the sensory nerve endings governing the sense of smell so that human beings can no longer smell these odors. Again let it be said that more modern work<sup>4</sup> has served to establish this previous work more firmly, and again the Nomis Corporation has not presented critical evidence to substantiate its claims.

A further consideration is that of the general physiologic effect of ozone on the human being—a thing which the Nomis Corporation apparently failed to consider. Scientific work has shown that ozone in sufficient quantities to be even partly effective causes definite harm to man<sup>5</sup> and is therefore not a 'tonic

Spectrogram of (A) corona on Nomis Pure Aire Unit (B) corona on homemade device

for the human body." Among other things ozone causes (1) irritation of the mucous membranes of the nose, throat and lungs, (2) headaches, (3) drowsiness, (4) fatigue and (5) burning sensations in the eyes. All these are noticed after exposure to concentrations of ozone which are below the level at which ozone is even partially effective. At the level at which ozone does have some small power to destroy germs and odors, these sensations are noticed within five to ten minutes and are of longer duration and greater intensity.

The Council draws from the foregoing discussion the following conclusions: (1) Ozone is effective (and then only slightly so) in such concentrations as are definitely injurious to the well being of man and (2) the Nomis Corporation either has a machine capable of doing harm to man or of being useless to man, points which the Nomis Corporation has not given critical evidence to disprove or confirm.

In view of the foregoing report the Council on Physical Therapy voted not to accept the Nomis Pure Aire Unit for inclusion in its list of accepted devices, since the Council believes that the marketing methods and advertising claims employed by the firm are inimical to the public welfare.

## ALCOHOLIC INTOXICATION AND PNEUMOCOCCIC INFECTION

Clinicians have observed for many years that alcoholic intoxication is a predisposing cause of pneumonia and that the death rate in pneumonia in alcoholic addicts is definitely higher than the mortality of abstainers from alcohol. Osler<sup>1</sup> believed that the most potent predisposing factor in pneumonia is the lowered resistance due to alcohol. A most convincing clinical report on alcohol as a predisposing factor in pneumonia was published in *THE JOURNAL* fifteen years ago by Capps and Coleman.<sup>2</sup> Among 3,422 cases of pneumonia at Cook County Hospital in Chicago they found that the mortality rate among the excessive drinkers was 49.87 per cent, among the moderate drinkers 34.4 per cent and among the abstainers or occasional drinkers 22.45 per cent.

Medical literature contains many reports of both clinical and experimental observations which point strongly to the fact that alcoholic intoxication lowers the resistance not only to pneumococcic infections but to other infections as well. This literature has recently been reviewed by Pickrell<sup>3</sup> of Johns Hopkins University. In 1884 Robert Koch reported observations that during cholera epidemics most of the people who became sick had been guilty of alcoholic excess. Koch followed his clinical studies by experimental work, in which he showed that intoxicated rabbits died sooner of cholera than did similarly infected nonintoxicated animals. Abbott<sup>4</sup> demonstrated that the resistance of rabbits to infection by *Streptococcus pyogenes* was diminished through the influence of alcohol and that the susceptibility of such animals to certain other types of infection was increased by alcoholic intoxication. Laitinen<sup>5</sup>

demonstrated unmistakably the deleterious effect of alcohol on the resistance of animals to anthrax, practically all his alcoholized animals died of anthrax, whereas most of those that had not been given alcohol recovered. In reviewing the literature, Pickrell was impressed by the fact that few of the studies had been adequately controlled and that none of them gave a satisfactory explanation for the effect apparently brought about by alcoholic intoxication. He therefore devised and with the assistance of Dr. Arnold R. Rich carried out an extensive series of experiments in an attempt to discover the mechanism by which this occurs.

In brief the experiments consisted of immunizing rabbits by intravenous injection of type I pneumococcus serum, then of intoxicating some of them with ethyl alcohol until stuporous and then of infecting all of them and the control animals with the same dose of type I pneumococci injected into the skin. In a type experiment twelve rabbits were immunized against type I pneumococci. In a few hours intoxication with alcohol was induced in six of these animals, and all of them, as well as the control animals, were injected in the flank with 0.1 cc. of an eight hour type I pneumococcus culture. In four hours the nonimmunized rabbits gave a positive blood culture and all such animals died within eighteen hours. The immunized rabbits which had been intoxicated showed a positive blood culture at from nine to ten hours and death occurred within twenty-four hours. The immunized rabbits which were nonintoxicated did not develop a positive blood culture and they survived. The immunized group which had not become intoxicated developed only a minute erythematous lesion at the site of injection. The nonimmunized rabbits which had not been intoxicated developed about the site of injection a large purpuric, edematous, hyperemic lesion which extended to the belly surface. In striking contrast, no macroscopic lesion developed in any of the intoxicated rabbits at the site of the injection. In all the nonintoxicated animals microscopic examination revealed a dense leukocytic infiltration at the sites of injection but in the intoxicated rabbits there was practically no leukocytic emigration, and bacteria swarmed in the tissues in the immunized as well as in the nonimmunized alcoholic animals. There was an abundant leukocytic exudate in the nonintoxicated immunized animals and no bacteria could be found in the sections about the site of injection after nine hours.

To determine whether a similar result would occur in the lung, four rabbits were immunized and in a few hours two of them were intoxicated with alcohol. These four, together with two normal control rabbits, were given into the trachea 0.2 cc. of the same type of pneumococcus culture. The normal control rabbits and the intoxicated nonimmunized rabbits showed a positive blood culture within five hours and they died within twelve hours. The immunized intoxicated rabbits did not develop septicemia until eighteen hours, and they

died at twenty-two and twenty-four hours respectively. The immunized rabbits which were not intoxicated did not develop a septicemia and were in excellent condition when killed later for comparison of their lesions with those of the other rabbits.

Another experiment was carried out to determine the effect of intoxication on the phagocytic power of the leukocytes. A suspension of pneumonot was injected into the pleural cavity of twenty-four rabbits, and hours later there was an abundant exudate in the pleural cavity rich in leukocytes. Then twelve of the rabbits were made profoundly intoxicated and after two hours a concentrated culture of an avirulent strain of pneumococci was injected into the pleural cavity. After forty-five minutes stained smears of the pleural exudate were made. The leukocytes in these smears were found to be engorged with pneumococci, and there seemed to be no difference between the intoxicated and the nonintoxicated animals with regard to the number of leukocytes containing bacteria or the average number of bacteria in them. Phagocytosis was very active in these pleural exudates. This experiment demonstrates that the effect of intoxication in destroying immunity is not due to paralysis of the phagocytic power of the leukocytes.

An experiment was performed to show the effect of intoxication on the motility of the leukocytes. Blood was taken from both patients and rabbits in alcoholic stupor and vital preparations were studied in the warm chamber; differential counts showed no difference in the number of nonmotile leukocytes in the blood of the intoxicated subjects as compared with the number of normal controls.

These and other experiments reported by Pickrell indicate that the loss of immunity during alcoholic intoxication is due to the failure of the leukocytes to emigrate. The motility of the leukocytes apparently is not affected nor is their phagocytic power. The failure of the leukocytes to emigrate in the intoxicated state appears to be due to the effect of intoxication on the vascular inflammatory mechanism. Previous investigators have shown that the normal reaction of the capillaries to an inflammatory incitant is dilatation, changes in the rate of blood flow through them and changes in the distribution of the blood cells whereby the red cells tend to occupy a position as a core in the center of the stream, while the leukocytes are segregated laterally along the capillary wall. Thus the leukocytes normally are brought into position for emigration before they become adherent to the endothelium and escape through the capillary wall into the surrounding tissue. In the intoxicated organism the margination of the leukocytes in the capillaries does not occur. The evidence seems clear that in the intoxicated organism the capillaries fail to respond to the presence of an inflammatory incitant with dilatation and increased permeability. In what manner intoxication acts to prevent the usual inflammatory changes in the capillaries is as yet obscure.

These experiments offer convincing evidence that alcoholic intoxication maintained at a point of stupor destroys resistance to infection with the pneumococcus in rabbits, even in animals previously rendered highly immune.

---

#### THE FIRST ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Early in the deliberations of the Council on Industrial Health its members determined to hold a series of conferences to aid in clarifying the objectives of the industrial health movement. The first Annual Congress on Industrial Health was conducted January 9 and 10 in Chicago.

Part of the Council's plan for the advancement of industrial health is a stimulation of clinical discussions on industrial medical problems through the state and county medical organizations. There has been no forum particularly designed for the consideration of non-clinical problems of administration and integration. These may on occasion be fully as troublesome as diagnosis and treatment. The first conference of the Council dealt with these problems. As discussions are continued and regular opportunity is supplied for expression of opinions on industrial health by all interested members in the profession, the usefulness of these conferences will become apparent.

The keynote of the first congress was contained in the report of the chairman of the Council on Industrial Health. Dr. Seeger pointed out that the practicing physician must attempt to orient himself in this expanding field. The aims and accomplishments of other organized agencies must be made plain. The progress of industrial medicine must be appraised periodically. Its scope and interrelationships must be constantly reemphasized and redefined. The program of this first conference undertook to express the points of view of organized medicine and of the principal professional, governmental and lay agencies responsible for the health of the working population.

Approximately 250 leaders in industrial health attended. Industrial medicine has progressed greatly in twenty-five years. Within the profession a career in preventive industrial practice is recognized increasingly as a worthy aim in itself. There was every indication that lay organizations welcomed the opportunity to learn at first hand the attitude which organized medicine takes toward industrial practice. There can be no essential incompatibility between their purposes and those of the medical profession which the conference table cannot solve. This method is much to be preferred to any legislative approach. Likewise it was frequently and emphatically expressed that organized medicine through both tradition and structure has a preeminent opportunity and responsibility to exert a salutary effect on standards and training in the sphere of industrial medical practice.

## Current Comment

### THE FOURTH OF JULY RECORD

Elsewhere in this issue (page 236) appears a summary of injuries due to Fourth of July fireworks in 1938. Last year after a lapse of twenty-one years a similar analysis was presented, because of the increase which was being shown by this form of injury. Again fireworks have been demonstrated as a serious menace to life and health, in fact, this year there were actually more individual accidents leading to death from fireworks than in 1937, in spite of the wide publicity given to the 1937 summary by newspapers and public-spirited organizations. The control of fireworks must originate in the legislatures of the respective states. With the present day ease of transportation, only statewide laws can be considered adequate, even their effectiveness is endangered by adjacent states which may lack control measures. In some states, such as Pennsylvania, Indiana and Missouri, the need for effective and enforced legislation is only too obvious. A repetition of the tragedies of 1938 can be construed only as gross negligence in relationship to a controllable situation.

### ELECTROLYSIS FOR SUPERFLUOUS HAIR

An increasing number of electrolytic instruments designed particularly to remove hair, moles and warts are appearing on the market. There is a growing tendency for laymen, unqualified by experience and training, to undertake the use of such apparatus. The electrolytic instruments may be found in beauty shops and in offices conducted by self-designated electrologists, hair specialists, lay dermatologists, depilatory experts and the like. Because of the seeming simplicity of the processes, people are often misled into believing that they are quite safe with these lay operators. Actually there are a number of reasons why such safety is not assured. First, untrained operators are apt to have little knowledge of aseptic technique. The importance of proper sterilization of the patient's skin, the operator's hands and arms and the needle holders and needles, as well as the proper precautions to avoid infections, are largely unknown to or may be disregarded by these technicians. Infection may be mild, such as a small pustule, or may result in abscess formation. Erysipelas has been known to develop around one of the infected regions. If the infection occurs in the nose, glabella or upper lip, it may cause death because of the direct venous communication between these areas and the lateral sinuses. When moles and warts are treated by lay operators there are additional dangers resulting from lack of diagnostic ability. As they are unable to differentiate between benign moles and those which are malignant or may become malignant neoplasms as the result of trauma during treatment, serious sequelae may follow. To avoid the hazards of infection and improper diagnosis the operator should have some understanding of anatomy, physiology, bacteriology, antiseptics and tissue tolerance to trauma, as well as the chemical reac-

tion involved in electrolysis and the physics and mechanics of the apparatus used. Pitting and scarring may result from the application of too much current or too long a treatment, as well as from improper insertion of the needle into the hair follicle. If the operator makes several stabs at a single follicle or treats too many hairs in a given area, infection and scarring may be expected to ensue. Because of the serious consequences that may result when electrolytic machines are misused, the Council on Physical Therapy approved an article on the subject by Dr. Anthony C. Cipollaro, which appeared in a recent issue of *THE JOURNAL*.<sup>1</sup> The article merits attention by every physician, since all of us are frequently asked for advice on this subject.

### DRUG ADDICTION

Although addiction to drugs has long been known, only recently has medical knowledge begun to play a part in the treatment of this condition similar to that enacted in the reforms which took place in the management of insanity during the last century. Certainly, as pointed out by Surgeon General Thomas Parran,<sup>2</sup> opium and its derivatives are by far the most important addicting drugs. The vast majority of the addicts want to be relieved of the habit, punishment alone is never effective, but these unfortunates have been despised and neglected by society. Now it is recognized that the excessive and continued use of narcotics, especially opiates, brings about changes in the physical constitution that must be corrected and that the continued use of these drugs denotes in many cases an emotional imbalance or disintegration of personality that must be corrected if permanent cure is to be effected. The rehabilitation of an addict requires time, during which, in addition to receiving special treatment, he should be encouraged to develop healthful habits of work and recreation. In connection with the two hospitals (at Lexington, Ky., and the newly dedicated institution at Fort Worth, Texas) now open for the treatment of drug addiction, laboratory studies have been designed to uncover the fundamental mechanism of addiction and the pathologic changes of function caused by narcotics. The establishment of these two government hospitals marks a definite step forward in the management of one of society's most difficult problems and offers hope that the permanent therapeutic results will, at least eventually, wholly justify this new venture.

<sup>1</sup> Cipollaro A. C. Electrolysis. *J A M A* 111: 2488 (Dec. 1) 1934.

<sup>2</sup> Parran Thomas. The Problem of Drug Addiction. *Pub Health Rep* 53: 2193 (Dec. 16) 1938.

<sup>3</sup> A narcotic addict desirous of entering the United States Public Health Service Hospital at Lexington, Ky., or Fort Worth, Texas for treatment is a voluntary patient will on application to the Surgeon General of the United States Public Health Service, Washington, D. C., be furnished the necessary blanks and instructions. A charge of \$1 a day is made but if an applicant is impecunious this charge will be waived on presentation of certain proof. In order to be eligible for treatment a person must be a citizen of the United States and be a habitual user of opium or coca leaves or their derivatives or of Indian hemp or peyote. A medical examination by a physician designated by the applicant or by a United States Public Health Service medical officer is required. Should the report of this medical examination indicate that the applicant is an addict the Surgeon General addresses a letter to him authorizing his admission any time within four weeks of the date of the letter. He cannot be confined without his consent. At the present time there are no accommodations for women patients but it is anticipated that such accommodations will be available early in 1940.

# ORGANIZATION SECTION

## AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

### OHIO STATE MEDICAL ASSOCIATION REPORT

The first summaries by states of the Study of the Need and Supply of Medical Care are now being received. One feature already forecast in the reports from county medical societies stands out even more prominently in the summaries for entire states—that is, the splendid cooperation received from affiliated agencies. Nearly every county medical society so far reporting has stated that a larger percentage of replies has been received from the eight questionnaires sent to welfare organizations, health departments, hospitals, nurses schools and colleges than from those sent to physicians and dentists. The Ohio State Medical Association reports the same results from an entire state.

This emphasizes one of the peculiarly valuable characteristics of the survey by the American Medical Association. While the study is conducted under the auspices of organized medicine, information is sought from every source that may be able to contribute any facts as to the need and supply of medical care in any locality. This characteristic is in strong contrast to the surveys that have been made by governmental and private organizations and which have been used as the basis of exaggerated reports of a lack of medical care and also of unjustified attacks on the medical profession for not providing such medical care. A large number of such surveys have almost completely ignored the largest source of authoritative information concerning medical care and the only source capable of judging the quality of that care. In the survey by the American Medical Association these organizations are especially urged to report any information which they may have as to a lack of medical facilities or as to the existence of individuals or classes of individuals who have desired and been unable to obtain medical care.

There are practicing physicians in every county in Ohio, but there are two counties in which the number of physicians is less than one for every 2,000 persons resident in the county, and this is considered to be an insufficient number. There are fifteen counties having a total population of 120,518 in which there are no hospitals, information is not furnished as to the extent to which hospital facilities are available to the residents of those counties from outside their boundaries.

There are two islands in Lake Erie in which, in accordance with a state law, the township trustees maintain a house as a residence of a resident physician in a township that is inaccessible from the mainland at some time of the year for any reason.

The Ohio State University College of Medicine operates a hospital with a bed capacity of 256 for the care of indigent persons from any part of the state. Legislative appropriations, however, have been insufficient to meet the hospital's operating expense; this condition has necessitated a reduction in the number of pay patients admitted. During 1937, 35 per cent of the patients were treated free, 23 per cent were part pay and 42 per cent were full pay.

The present capacity of state institutions for mental and nervous diseases, the feeble-minded and the epileptic is insufficient. Every one of the twelve mental hospitals in the state is overcrowded. The total rated capacity of these institutions is 21,478 and the average census is 25,412. During a special session of the legislature in 1937 a bill was passed creating a public institutional building authority for the construction and improvement of buildings for the use of state institutions. This bill contemplates an expenditure of \$7,500,000 for this purpose, to be matched by federal funds. However, the legislature failed to make the necessary appropriation. These institutions are available not only to the indigent, since those who are financially able to do so are required to pay \$5.50 a week. In the case of the feeble-minded, the county from which the indigent patients are committed must bear the expense.

The Ohio State Medical Association has summarized the agencies concerned with medical care which operate on a statewide basis. Four departments of the state government devote all or part of their efforts to health or medical service, namely the State Department of Health, the State Department of Public Welfare, the State Department of Education and the State Industrial Commission.

### DEPARTMENT OF HEALTH

The Ohio Department of Health is composed of the following divisions and bureaus: Division of Administration, which includes the Bureau of Health Organization, Division of Communicable Diseases which is composed of the Bureau of Tuberculosis and the Bureau of Venereal Diseases, Division of Hygiene, including the Bureau of Child Hygiene, the Bureau of Dental Hygiene, the Bureau of Occupational Diseases and the Bureau of Hospitals, Division of Laboratories, Division of Vital Statistics, Division of Sanitary Engineering and the Division of Nursing.

The Public Health Council, a quasi-judicial body, consists of the State Director of Health and four members, two of whom "shall be physicians who shall have had training or experience in sanitary science." This board has no administrative or executive duties. It is empowered to make sanitary regulations of general application throughout the state, consider appeals from decisions of the State Director of Health relating to the approval or disapproval of plans for local sanitary projects such as sewage disposal and water supply, and to make recommendations to the State Director of Health concerning any matters relating to the improvement and preservation of public health.

Since the inauguration of the Federal Social Security program in February 1936 and the influx of federal funds from the United States Children's Bureau and the United States Public Health Service, the activities of the State Department of Health have been amplified considerably. The personnel of the department has been increased from ninety-one to one hundred and sixty-seven. In 1935 there were seventy-six full-time health units in Ohio, forty counties and thirty-six cities, there

are now eighty-eight full-time units, fifty counties and thirty-eight cities, and in these districts there are thirty-three sanitary engineers and trained sanitarians. Funds have been made available for the training of personnel in public health administration.

In general it can be said that during the past four years the State Director of Health has cooperated fully with the Ohio State Medical Association. Before new programs have been initiated, questions of policy have been discussed with officials of the State Medical Association and the Association's Committee on Public Relations and Economics. In local health activities, such as immunization and school health programs, local health officials have been requested by the state department to work with the county medical societies, a procedure which has usually been followed.

As in all governmental departments, political interference has been a handicapping factor in the administration of the State Department of Health. A change in the state administration invariably means a new director. There has been no continuity in the office. In an attempt to remedy this situation, legislation will be introduced at the 1939 session of the legislature, proposing to set up a commission of six members, including three physicians, serving for six year terms, which would submit the names of five qualified physicians from which the governor would select one to serve as director. Such appointee would be removable only for cause. It is believed that this method of appointment will result in a minimum of political interference.

#### DEPARTMENT OF PUBLIC WELFARE

Medical programs for dependent and crippled children and the blind have been developed by the Division of Public Assistance in the State Department of Public Welfare. The approximate number of beneficiaries under this program is 3,200 crippled children, 31,000 dependent children in 11,000 families, and 4,000 blind persons.

The program for medical care for dependent children was worked out by officials of the Division of Public Assistance in cooperation with the Committee on Public Relations and Economics of the Ohio State Medical Association. After details of the plans were agreed on, local county medical societies were requested to assist in the formation and administration of the program in the various counties in the state. According to officials of the division, about one half of the eighty-eight counties in the state have established ADC medical and health programs. Progress in the other counties has been hindered by lack of local funds. Under the Bureau of Charities, surgical treatment and hospitalization have been provided for indigent crippled children throughout the state for many years. Only recognized orthopedic surgeons are permitted to do this work. An Advisory Professional Committee has been of great assistance in the supervision of this program.

Medical treatment of the needy blind has been administered by the Bureau of Aid to the Blind, which has sought the advice of the officials of the Ohio State Medical Association. An advisory committee of ophthalmologists has assisted in the development of this program. Since the bureau has been receiving federal Social Security funds it has concentrated on early and corrective treatment to prevent total blindness.

The Division of Aid to the Aged has no definite program for the medical care of 112,000 old-age pensioners. In the suggested budgets to its wards, the

division advises that \$1 per month of the average monthly pensions, which are approximately \$27, be allocated for medical care. Obviously this is inadequate even if the old-age pensioners set aside that amount each month.

#### STATE INDUSTRIAL COMMISSION

Every employer of three or more persons in Ohio is required to pay premiums to the State Industrial Commission for the purpose of providing compensation to workmen and their dependents for death, injuries or occupational diseases sustained in the course of employment. Awards include payment for the medical and hospital treatment necessitated by any such injuries. Injured workmen are permitted to choose their own physician.

Payment for medical services is on the basis of a fee schedule which went into effect Feb. 1, 1926 following conferences between officials of the commission and a special committee of the Ohio State Medical Association. Few complaints have been made as to the fees allowed. There has been general dissatisfaction with the slowness of administrative procedure, particularly the handling of correspondence. It is believed that this situation could be remedied if the legislature would appropriate sufficient funds to enable the commission to improve its personnel.

Relations between the Industrial Commission and officials of the State Medical Association have been friendly throughout the years. While the Medical Section has been handicapped by lack of sufficient funds, there has been improvement in its administration and personnel in the last three years.

During 1937, Ohio physicians received \$3,278,434 from the Workmen's Compensation Fund for services rendered to injured workmen. Payment for hospital and nursing care for the same year totaled \$1,293,141.90.

Since Jan. 1, 1934, the Industrial Commission has been authorized to set aside an amount not to exceed 1 per cent of the monies contributed to the State Insurance Fund for the investigation and prevention of industrial accidents and diseases. This program of education and inspection is carried on by the Division of Safety and Hygiene, which conducts safety campaigns and enforces rules and regulations for the health and safety of employes.

#### DEPARTMENT OF EDUCATION

During 1937 a Bureau of Health and Physical Education was reestablished in the State Department of Education for the purpose of developing a well rounded program of physical education and health instruction in the public schools. During the school year 1936-1937 health instruction was included in the curriculum of 75.73 per cent of Ohio schools. Only 52.22 per cent required physical examinations before entrance.

A campaign is being conducted in the schools and before lay groups on the evils of narcotics, particularly marijuana, and alcoholic liquor.

The Ohio Congress of Parent-Teachers, through its local units, has sponsored preschool physical examinations and school health programs. State officials of the Parent-Teachers' Association have frequently sought the advice of the Ohio State Medical Association in planning health phases of their program. It has always been the policy of this organization to have the local Parent-Teachers' Associations work out the method of conducting these preschool physical examinations with the local county medical societies.

The Ohio Public Health Association, an affiliate of the National Tuberculosis Association, has been concerned principally with an educational campaign against tuberculosis through the sponsorship of local anti-tuberculosis societies. These activities are financed through the sale of Christmas seals and private donations. The association has always been active in advocating adequate financing of health departments and higher standards of public health personnel.

The Ohio Society for Crippled Children, an organization financed by private donations, has been responsible for the rehabilitation of many needy crippled children throughout the state.

The American Legion, Veterans of Foreign Wars, the Masonic Order and other fraternal orders, including luncheon clubs such as Rotary, Kiwanis, Lions and Mercator, and the Junior Chamber of Commerce have supported various types of local health programs. They include support of bond issues for new hospitals and the like, raising funds for medical and surgical treatment of worthy persons, and furnishing of milk, provision of eye glasses for indigent children and others.

#### POOR RELIEF LAWS

Ohio is operating under a system of poor relief which is woefully in need of revamping. Laws dividing the responsibility for the care of the indigent among eighty-eight counties, 110 cities and 1,344 townships and more than 7,000 public officials have been in effect, with only slight variations, since 1853. The situation was further complicated in 1932 with the entrance of the state into the financing and administration of poor relief, appointment of a state relief commission, and a parade of "stop-gap" relief legislation during the past six years. The situation has been generally unsatisfactory to the medical profession.

An attempt will be made at the coming session of the state legislature to repeal the antiquated relief statutes and to provide for the concentration of all public assistance administration in one county-wide agency. The proposed legislation contemplates a medical bureau under medical supervision in this agency, which would supervise the provision of medical care to recipients of all types of public assistance.

The total amount of public money expended in Ohio during 1937 for all types of public assistance and general relief was \$142,436,000. Of this amount the federal government provided approximately three fourths, the state of Ohio a little more than one sixth, and local governments about one twelfth. WPA accounted for slightly over one half of the expenditure, social security nearly one fourth, general relief about one eighth, and miscellaneous federal agencies about one eighth. No figures are available to show what proportion of these funds was spent for medical care.

#### FARM SECURITY ADMINISTRATION

There are 26,302 families, representing approximately 110,000 dependents, receiving assistance from the Farm Security Administration in Ohio. Following a series of conferences between officials of the Farm Security Administration and the Ohio State Medical Association an agreement was reached as to the basic features which should be included in any local program for the medical care of Farm Security Administration clients.

A medical program for Farm Security Administration clients has been arranged with the cooperation of the county medical societies in the following thirteen

counties: Geauga, Portage, Perry, Pike, Clermont, Fayette, Madison, Champaign, Union, Delaware, Logan, Hardin and Paulding.

#### MOTOR VEHICLE INJURY ACT

Since 1933 the sum of 19 cents for each motor vehicle registered in the state has been placed in a special fund administered by the Bureau of Motor Vehicles for the purpose of reimbursing hospitals for the expense of caring for indigents injured in motor vehicle accidents. During 1937 claims paid from this fund numbered 1,914, in an amount of \$228,162.24.

#### GROUP HOSPITALIZATION

Under the Ohio statutes, group hospital associations on a county-wide basis are exempted from having to qualify under the state insurance laws. Unsuccessful attempts have been made at recent sessions of the state legislature to permit these associations to insure their clients against hospitalization expense incurred outside the county in which the association is located. At the present time group hospitalization associations are operating in the following Ohio counties: Cuyahoga, Lucas, Summit, Mahoning, Licking, Scioto, Stark, Erie, and Franklin. The number of subscribers is more than 200,000, of whom 150,000 are located in Cleveland and Cuyahoga County.

#### GENERAL OBSERVATIONS

1 In general, Ohio has an adequate number of physicians, and medical facilities are probably more plentiful and efficient than in many other states. However, there is need for a more equitable distribution of physicians and facilities between urban and rural counties in some parts of the state.

2 The medical relief program in Ohio has not been entirely adequate, both from the standpoint of the amount of money made available for this purpose and the compensation actually paid to physicians. However, this is a state and local program and one which at the present time is receiving serious consideration from all groups concerned, including the state legislature. Despite the inadequacy of the program there is plenty of evidence to support the statement that there are very few persons in Ohio actually suffering from lack of medical attention for serious disabilities.

3 The medical profession is making a constructive effort to meet the various problems. A special committee of the Ohio State Medical Association has made a study of the poor relief statutes and is now formulating legislation which, if enacted, will simplify the administration of medical relief through the coordination of the various separate agencies into one county board responsible for the medical care of all persons receiving public assistance.

In a number of the larger counties, notably Cuyahoga, Hamilton, Summit, Montgomery, Mahoning and Franklin, the local medical societies are working on plans designed to make medical service more readily available to all the people, particularly indigents and those in the low income groups. Plans developed by the county medical societies are reviewed by a special coordinating committee of the Ohio State Medical Association, which hopes to evolve a flexible plan or plans which can be adapted to local needs throughout the state.

4 The state medical association is working with other interested statewide groups in a movement to make the administration of the State Department of Health more efficient through higher standards for

personnel, a minimum amount of political interference, and by making the selection of the state health director a merit appointment, with continuity of office, rather than a political appointment subject to change with each new state administration.

The summary by the state medical association was accompanied by reports and other material from the various agencies concerned in medical care. A further analysis of reports from thirty-four counties which have been received by the Bureau of Medical Economics showed that, according to returns from 1,400 physicians, these physicians had rendered medical ser-

vice without pay to 138,000 persons in their offices or at hospitals and clinics. These same physicians had given 128,584 free hours to hospitals and clinics. This was for a population of 2,860,000. Since only about 50 per cent of the physicians returned questionnaires, the free service thus listed is by no means a full measure of all the care that was given without payment. It would seem to be a fair estimate—based on the returns received, which constitute a far larger sample of the population than in any comparable survey—that at least 10 per cent of the population in these counties received medical care without payment.

## ACTION OF HOUSE OF DELEGATES OF MICHIGAN STATE SOCIETY

At a special session in Detroit January 9 of the house of delegates of the Michigan State Medical Society the council made a report on group hospital service and group medical care plans, which was in part, as follows:

At the seventy third annual meeting of the Michigan State Medical Society, held in Detroit last September the House of Delegates received considerable material from the Committee on Distribution of Medical Care covering (a) group hospitalization and (b) group medical care plans. The House of Delegates Reference Committee presented the following report on the Committee's activities:

We approve the principle of voluntary hospital insurance provided that hospital insurance be so defined that it does not include professional services by a doctor of medicine. We also recognize the merits of certain principles in voluntary health insurance and we therefore urge that recommendation IV of the General Program of Medical Care as defined by the American Medical Association September 17 be adopted in principle by the Michigan State Medical Society. We further recommend that the Committee on Distribution of Medical Care continue with more detailed studies of an acceptable insurance program, the results to be presented to a special meeting of the House of Delegates in the near future.

The members of the council have become convinced that the membership of the society generally, throughout the state, desires to put into active operation a statewide system for the prepayment of medical care and hospital service through the pooling of funds therefor. The public desire is evidenced in numerous ways. In the problem of bringing adequate hospital service and medical care within the reach of every citizen of the low income group some have mistakenly supposed that the doctors of medicine had to assume the whole burden, furnish the plan, raise the money, take all the risks and do all the work. By enlisting the community in such an enterprise the greatest barrier against governmental interference would be built. Therefore the Committee on Distribution of Medical Care presents to us a statewide community health service founded on the development of lesser community groups and based on the principles laid down in the plans developed by the Committee on Distribution of Medical Care.

The projected plan of group medical care contains matters to which the council directs your particular attention: (1) the plan is open to all licensed doctors of medicine in the state who agree to the rules and regulations; (2) the subscribers have complete freedom of choice; (3) the control of the administration and policy of medical service is to be vested in the medical profession; (4) the medical services are to be paid out of available pooled funds on a unit system. Such a system affords freedom of action, insures the success of the plan and it dues are not placed at a proper figure they can be rectified at any time. The situation is entirely different from that where the doctors agree to work on a unit system with dues fixed by an intervening agency over which the doctors have no control. The true insurance principle—definite rates and definite benefits—is preserved under this system.

So far as possible district administration will be put on an autonomous basis. The council suggests that discussion here should be centered on fundamentals and not on details. In the deliberations of this body it will be impossible to work out or discuss details in the inauguration of a plan designed

for statewide coverage eventually. Details must be entrusted to representatives from various geographic areas and differing conditions of medical practice.

The council recommends that this house of delegates after due consideration and discussion instruct the council to take the necessary actions to create and put into operation an organization or organizations containing the essential provisions embodied in the tentative drafts as presented by the Committee on Distribution of Medical Care.

### Action of House of Delegates

The house of delegates approved the principles of group hospitalization, approved the principles of group medical service and empowered the council in cooperation with the hospitals and civic groups to proceed with the establishment of plans embodied in the foregoing principles.

The following report of the reference committee on Reports of Standing Committees was approved by the house of delegates:

The matters contained in the material presented by the Committee on Distribution of Medical Care have been considered and your reference committee begs to report as follows. It has reaffirmed the principles endorsed by this body last September relative to group hospitalization and sickness insurance schemes and recommends that all future action in group hospital and medical service plans conform to these principles.

It then considered separately for purposes of clarity (1) group hospitalization and (2) group medical service.

### GROUP HOSPITALIZATION

Your reference committee recommends:

1 That the council continue its efforts with the Michigan Hospital Association and the representatives of labor, industry, agriculture, religious and educational organizations, community councils and other interested groups to obtain a non-profit group hospitalization plan sponsored jointly by the medical profession, the hospitals and the public.

2 It is further recommended that the council be empowered to cooperate with or assimilate any one or more of the group hospitalization organizations which are now formed and may be formed to transact such business.

### GROUP MEDICAL CARE

Your reference committee by a majority vote recommends that we empower the council to cooperate with labor, industry, agriculture, religious and educational organizations, community councils and other interested groups in the formation of a non-profit group medical care organization.

The following additional motion was passed by the house of delegates:

The council of the Michigan State Medical Society is empowered to use its judgment in the matter of cooperating in introducing necessary legislation in the legislature of the state of Michigan at the present session to make it possible to legally handle both group hospitalization and group health insurance.

## OFFICIAL NOTES

## RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "You Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p m eastern standard time (1 p m central standard time, 12 noon mountain time, 11 a m Pacific time).<sup>1</sup>

<sup>1</sup> Owing to program conflicts there will be no Chicago broadcast of the network program. Instead a recording of the program will be broadcast over station WENR at 8 p m each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

These programs are broadcast on what is known in radio as a sustaining basis, that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next six programs to be broadcast, together with their dates and their topics, are as follows:

January 25	Smallpox and Diphtheria
February 1	Preventing Epidemics
February 8	Avoiding Arthritis
February 15	Healthy Hearts
February 22	Cancer Can Be Cured
March 1	Diabetes

## MEDICAL LEGISLATION

## Medical Bills in Congress

**Bills Introduced**—S 85, introduced by Senator White, Maine, proposes to grant pensions to male nurses who served under contract during the Spanish-American War. S 471, introduced by Senator Murray, Montana, proposes to authorize an initial appropriation of \$5,000,000 and for each fiscal year for four consecutive years a sum "sufficient to carry out the purposes of this act," to enable each state to make adequate provisions for hospital beds for tuberculous patients. The bill contemplates that the money to be appropriated shall be allotted by the United States Public Health Service to the states that submit approved plans. S 497, introduced by Senator King, Utah, proposes to provide for the incorporation of certain persons as "Group Hospitalization, Inc." The corporation is to be authorized (a) to enter into contracts with individuals or groups of individuals to provide for hospitalization of such individuals, on the payment of specific rates or premiums, and to issue to such individuals appropriate certificates evidencing such contracts; (b) to enter into contracts with hospitals for the care and treatment of such individuals, in accordance with the terms of such certificates; and (c) to cooperate, consolidate or contract with groups or organizations interested in promoting and safeguarding the public health. H J Res 103, introduced by Representative Coffey, Washington, proposes to authorize the United States Public Health Service to make a survey of the conditions in the United States with respect to the importation, production, distribution and use of narcotics. The bill contemplates that the Surgeon General of the Public Health Service shall make a report to Congress and recommend legislation. H R 38, introduced by Representative Dowell, Iowa, proposes to authorize an appropriation of \$400,000 to construct a 300 bed patient capacity addition to the existing veterans' facility at Des Moines, Iowa, for the treatment of general medical and surgical disabilities. H R 42, introduced by Representative Fitzpatrick, New York, proposes to amend the Social Security Act so as to provide for the payment of benefits to permanently and totally disabled individuals. H R 77, introduced by Representative Maas, Minnesota, proposes to authorize an appropriation of \$425,000 to construct a domiciliary building of 350 bed capacity at the veterans facility, Fort Snelling, Minn. H R 101, introduced by Representative O'Day, New York, proposes to amend the Social Security Act so as to include under its unemployment and old-age provisions employees in nonprofit organizations. H R 114, introduced by Representative Voorhis, California, proposes to establish a Cooperative Home Board and a system of Cooperative Home Associations. No member is to be accepted in such an association until he reaches the age of 62 years. Membership to be sold at not less than \$2,000. will entitle the member to housing, food, medical attention and other living necessities for the term of the membership. The United States Public Health Service, the bill contemplates will be authorized and directed to supply and supervise the medical service which is to be made available to association members and to supervise

the sanitary facilities of the association home units. H R 128, introduced by Representative Arends, Illinois, proposes to establish service origin connections, for veterans of the World War, for spastic paralysis, chronic arthritis, chronic rheumatism or chronic heart disease not the result of the veteran's own misconduct. H R 129, introduced by Representative Arends, Illinois, proposes to authorize an appropriation of \$787,500 to construct a 175 bed patient capacity addition to the veterans' facility at Dwight, Ill., for the treatment of general medical and surgical disabilities. H R 172, introduced by Representative Knutson, Minnesota, proposes to amend the Social Security Act to provide grants to states for furnishing aid to needy individuals who are physically handicapped. H R 204, introduced by Representative Bradley, Pennsylvania, proposes to authorize an appropriation of \$2,500,000 to construct a veterans' hospital for the Philadelphia area. H R 245, introduced by Representative Culkin, New York, proposes to impose an additional tax of 10 cents per pound on oleomargarine. H R 246, introduced by Representative Culkin, New York, proposes to prohibit not only the importation and interstate transportation but also the manufacture, sale, offering for sale or possession for sale of (1) any oleomargarine, margarine, butterine, or other substitutes for butter, manufactured from any fat other than that of milk or cream, and (2) any milk or cream or substitute therefor which contains any fat or oil other than that of milk. H R 295, introduced by Representative Parsons, Illinois, H R 922, introduced by Representative Spence, Kentucky, and H R 1951, introduced by Representative Bland, Virginia, propose to create a Division of Water Pollution Control in the United States Public Health Service. H R 802, introduced by Representative Jenkins, Ohio, proposes to provide that where an honorably discharged veteran suffers or has suffered an injury or contracted a disease and an emergency develops requiring immediate hospitalization on account of such injury or disease, and no veterans' facility is feasibly available and delay would be hazardous, the Administrator of Veterans' Affairs is authorized to pay the reasonable value of such service received from sources other than the Veterans' Administration. H R 889, introduced by Representative Rogers, Massachusetts, proposes to authorize an appropriation of \$1,400,000 to construct a new veterans' hospital and diagnostic center at or near Boston. H R 891, introduced by Representative Murdock, Arizona, proposes to authorize an appropriation of \$500,000 to erect additional buildings for veterans at Tucson, Ariz., to take care of at least 200 general medical patients. H R 902, introduced by Representative Smith, Washington, proposes to provide hospitalization, without charge for certain employees in the Bureau of Marine Inspection and Navigation of the Department of Commerce and for licensed local pilots of the United States at hospitals and other stations of the United States Public Health Service. H R 1008, introduced by Representative Welch, California, proposes to confer on certain persons who served in the Quartermaster Corps or under the jurisdiction of the Quartermaster General during the War with Spain, the Philippine Insurrection or the China Relief

Expedition the benefits of hospitalization and the privileges of soldiers' homes. H. R. 1776, introduced by Representative Bland, Virginia, proposes to provide for the assignment of medical officers of the Public Health Service for duty on vessels of the Coast and Geodetic Survey. H. R. 1800, introduced by Representative Maloney, Louisiana, proposes to authorize an appropriation of \$1,200,000 to construct in New Orleans or adjacent thereto, a 300 bed patient capacity veterans' hospital for the diagnosis, care and treatment of general medical and surgical disabilities. H. R. 1813, introduced by Representative Boland, Pennsylvania, proposes to authorize an annual appropriation of \$11,580,000 to enable each state to establish, extend and improve services for educating physically handicapped children. H. R. 1834, introduced by Representative Colmer, Mississippi, proposes to extend the benefits recorded veterans of the Spanish American War to contract veterinarians. H. R. 1945, introduced by Representative Allen, Louisiana, proposes to authorize an appropriation of \$450,000 to construct a 300 bed patient capacity addition to the veterans' facility at Alexandria, La., for the care and treatment of general medical, surgical and neuropsychiatric disabilities. H. R. 1960, introduced by Representative Izac, California, proposes to amend the Social Security Act to provide assistance for needy individuals who are permanently crippled. H. R. 2000, introduced by Representative Thomas, Texas, proposes to amend the Social Security Act to provide for grants to the states for assistance to needy incapacitated adults. H. R. 2003, introduced by Representative Van Zandt, Pennsylvania, proposes to authorize an appropriation of \$2,500,000 for the construction of a veterans' hospital with a capacity of at least 800 beds in the area of Blair, Centre and Clearfield Counties, Pa., for the accommodation of veterans entitled by law to such facilities. H. R. 2423, introduced by Representative May, Kentucky, proposes to establish a United States postgraduate medical and surgical college and research institute to provide properly trained medical, surgical and health personnel for the military, naval and public health services and to coordinate and improve health research activities of the federal government. The United States Medical and Surgical College, it is proposed, will be located in the District of Columbia and graduates of accredited medical and surgical colleges may be admitted to the institute for training for army, navy or public health work on designation by senators and representatives in Congress. Such trainees are to receive, it is proposed, \$1,200 a year while in training in the institute. The institute is to be authorized to provide medical, surgical and clinical facilities for the diagnosis and treatment of all types of illness and physical and mental disabilities. Such facilities are to be made available to all patients of any age, but no patient may be admitted whose income is in excess of \$1,000 a year except in police cases and in cases of emergency arising from accident. All medical, surgical and public health research activities conducted by or under the jurisdiction of the federal government with respect to foods, drugs, alcoholic liquors, maternal and child welfare, and medicine and surgery are to be under the jurisdiction of the board of regents of the institute. An appropriation of \$10,000,000 is to be authorized for the construction and improvement of buildings and equipment for the use of the institute and annually such sums are to be authorized as may be necessary to carry out the duties and functions of the institute and the board of regents. H. R. 2540, introduced by Representative Smith, Washington, provides that, for pension purposes, any person who served under contract with the War Department as acting assistant or contract surgeon during the Spanish American War shall be considered to have been in the active military service of the United States for the period of such contract service.

#### District of Columbia

**Bills Introduced**—H. R. 73, introduced by Representative Lemke, North Dakota, proposes to prohibit the making of any form of vaccination or inoculation a condition precedent to admission to any public or private school or college, or the exercise and enjoyment of any right or privilege, in the District of Columbia. H. R. 278, introduced by Representative Smith, Virginia, proposes to regulate the practice of optometry in the District of Columbia. The bill defines the practice of optometry to mean the science and art devoted to the examination of the eyes,

the analysis of the ocular functions and the employment of preventive or corrective "optometric methods and agents for the relief of visual and ocular anomalies."

#### California

**Bills Introduced**—S. 79 and A. 32 propose to make it unlawful for "the county clerk of any county to issue a license to marry to any person unless there is on file with him a certificate, signed by a physician, certifying that the applicant has" on a specified date not more than twenty days prior to the application "been given examination as is necessary for the discovery of venereal disease and that, in the opinion of the physician, the applicant is either not infected with a venereal disease or is not" in a stage of any such disease which is or may become communicable." The bill proposes that the examination referred to in the certificate include a thorough physical examination a Kahn or Wassermann test for syphilis, a dark field test where indicated, or any other recognized test for syphilis approved by the state department of public health, and a microscopic examination for gonococci where indicated. S. 80 proposes to require every physician or other person engaged in antepartum attendance on a pregnant woman to obtain a specimen of her blood within thirty days after the first professional visit and to submit the specimen to the laboratory of the state department of public health or to a laboratory approved by the department, for the performance of a Kahn, Wassermann or other standard laboratory blood test for syphilis. A. 10 and A. 33, to amend the Retail Sales Tax Act of 1933, propose to exempt from the tax imposed by the act "the gross receipts from sales of all medicines and preparations recognized in the United States Pharmacopoeia or National Formulary for internal or external use, and any substances or mixture of substances intended to be used for the cure, mitigation or prevention of disease of man." A. 11 and A. 34 to amend the Use Tax Act of 1935, propose to exempt from the tax imposed by that act "all medicines and preparations recognized in the United States Pharmacopoeia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation or prevention of disease of man."

#### Illinois

**Bill Introduced**—S. 9, to amend the old age assistance law, proposes to increase the benefits paid recipients "not less than \$5 nor more than \$15 per month for medical services actually rendered to such recipient, provided that such additional allowance shall only be paid while such recipient actually needs such medical care." Under the present paupers' act it is the duty of the appropriate poor relief official to supply at the expense of the county or town necessary medical care not only to poor and indigent persons but also to any other person who does not have "money or other property to pay his board, nursing and medical aid." What effect the enactment of S. 9, which would provide aid by state provided funds, would have on local aid is not clear.

#### Massachusetts

**Bills Introduced**—H. 60, to supplement the medical practice act, proposes to require every licensed physician to register annually with the department of registration in medicine and to pay an annual fee of \$2. H. 61, to amend the medical practice act, proposes to strike out the provision that no more than three members of the board of registration in medicine shall at one time be members of any one chartered state medical society. H. 69, to amend the pharmacy practice act, proposes to require applicants for licenses to practice to be graduated from schools or colleges of pharmacy approved by the board of registration in pharmacy. H. 70, to amend the pharmacy practice act, proposes to give the board of registration in pharmacy discretionary power in granting permits to stores to transact a retail drug business. Under the present law the board has no discretion in the matter and must grant a permit with respect to an application made in proper manner. H. 73 proposes to require the physician in attendance at the birth of a child born with visible congenital deformities or birth injuries to report within thirty days after birth to the state department of public health and the city or town clerk of the place where the birth occurred. H. 74 proposes to require the appropriate clerk or registrar, when an application for marriage or a license to marry is made to him, to hand each applicant such literature concerning gonorrhea and

syphilis and the importance of premarital examination as may be furnished for that purpose by the state department of public health. H 75 is a proposal to make the laws of Massachusetts correspond generally with the provisions of the new federal food, drug, cosmetic and therapeutic devices law relating to food and drugs.

#### New York

**Bill Introduced**—A 57 and S 74, to amend the law in relation to cadavers, prohibits the delivery to the medical colleges and universities of the state by any hospital, prison, reformatory, asylum, almshouse or morgue of the corpses of recipients of old age assistance whose burial cost is provided for by the public welfare law.

#### Oklahoma

**Bill Introduced**—H 76 proposes to authorize the state commissioner of health to appoint one regularly licensed physician for each county in the state to give medical treatment free of charge to such persons as make affidavit that they are unable to pay for such medical treatment. Such physicians are to be paid from \$150 to \$200 a month, may not engage in the private practice of medicine, are to be furnished an automobile by the state, and are to receive drugs, medicines, bandages and medical equipment on requisition to the state commissioner. Such physicians are not to perform major surgical cases, which are to be referred to state hospitals.

### Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

#### CALIFORNIA

**Cancer Survey**—A survey to determine the incidence of cancer in San Francisco and Alameda counties will be carried out by the U. S. Public Health Service. The survey was to begin January 1 and continue for three months. The county medical societies are cooperating. It is planned to send a letter to each physician asking for certain information concerning malignant conditions seen during 1938.

**Society News**—A symposium on tuberculosis was presented before the Los Angeles County Medical Association January 5 by Drs. Reginald H. Smart, Jacob J. Singer and Frank S. Dolley. The Los Angeles Surgical Society was addressed among others January 13 by Dr. William H. Snyder, Jr. on 'Spontaneous Hematoma of the Rectus Muscle, Simulating the Acute Abdomen'. 'Medicine Tomorrow' was the theme of a symposium before the Hollywood Academy of Medicine January 12 with Drs. Donald J. Frick and Egbert Earl Moody and Mr. S. K. Cochems, chairman, board of trustees, councilor and executive secretary respectively of the Los Angeles County Medical Association, as the speakers.

#### DISTRICT OF COLUMBIA

**Campaign Against Cancer**—An educational program on cancer control will be carried on in the District by the Medical Society of the District of Columbia in cooperation with the Women's Field Army for the District, the health department, the local council of social agencies and the American Society for the Control of Cancer. Lectures will be given by members of the medical society before luncheon clubs, civic bodies and similar organizations. The action followed a report by the society's subcommittee on cancer control, showing an increase in cancer mortality.

**Psittacosis in Washington**—Three cases of psittacosis were recently reported in Washington. Two of the persons developed symptoms November 9 and 16 and the third December 2. Two love birds were purchased by the family of the patients from a local merchant October 23. One of the birds died November 11 and the other November 16. An inspection of unsold birds at the merchant's place of business showed that there were three sick ones, these in addition to 109 others were destroyed. According to *Public Health Reports*, it is worthy of note that the pathologists of the National Institute of Health reported that the psittacosis virus was found also

in apparently healthy birds of these shipments. All the love birds involved came from a single source in southern California. In seven other shipments from different sources in California no sick birds were found, it was stated.

#### FLORIDA

**Florida Midland Medical Society Disbands**—Since the Southwest Medical District Society (D) of the Florida Medical Association covers territory identical with that of the Florida Midland Medical Society, the latter, after twenty-two years' service, has decided to disband. The name of the independent society will be perpetuated in the form of a midsummer social assembly for members and their families.

**Special Society Meeting**—At the third annual meeting of the Gulf Coast Clinical Society in Pensacola recently the speakers included Drs. Charles W. Mayo, Rochester, Minn., on "Factors Influencing Prognosis of Cancer of Colon", James S. McLester, Birmingham, Ala., "Recent Discoveries in the Science of Nutrition", Guy A. Caldwell, New Orleans, "Post-reduction Treatment of Simple Fractures," and Robert B. McIver, Jacksonville, on "Plastic Surgery of the Renal Pelvis". Dr. James H. Dodson, Mobile, was chosen president, Drs. Edward C. Parker, Gulfport, Miss., and John S. Turberville, Century, vice presidents, and Dr. Clyde C. Rouse, Mobile, secretary-treasurer, succeeding Dr. Jacques H. Baumhauer, Mobile. The next annual session will be held in Mobile, Ala.

**Clinical Conference**—The Florida Medical Center, Venice, will sponsor a clinical conference January 23-24. The speakers will include Drs. John B. Lauricella, New York, on "History of Industrial Medicine", Custis Lee Hall, Washington, "Ewing's Tumor", Joseph F. Londrigan, Hoboken, N. J., "History of Rehabilitation in State of New Jersey", Temple S. Fay, Philadelphia, "Presence of Intramedullary Cord Tumors in Chronic Scoliosis", and Arthur Krida, New York, "Treatment of Congenital Dislocation of the Hip in Infancy". Out of state speakers participating, among others, in a symposium on arthritis included Drs. Frank L. Eskridge, Atlanta, Ga., Charles H. Slocumb, Rochester, Minn., and Robert L. Preston, New York. Dr. Fred Albee, New York and Venice, will discuss elongation of lever at the hip for infantile paralysis.

#### IDAHO

**Personal**—Dr. Marion W. Caskey, Lewiston, has resigned as health officer of the North Central Idaho health district, composed of Nez Perce, Latah and Clearwater counties.

**Hospital News**—A new \$120,000 dormitory and clinic building was to be dedicated at the state mental hospital at Orofino December 20. It will provide space for 200 patients.

#### ILLINOIS

**District Meeting**—Dr. Sidney A. Smith, Chillicothe, was elected president of the North Central Illinois Medical Association at its sixty-fifth annual meeting in LaSalle December 6. He succeeded Dr. Wendall A. Potter, Sandwich. Vice presidents are Drs. Howard P. Sloan, Bloomington, and John F. Lewis, LaSalle, Dr. George A. Dicus, Streator, was reelected secretary-treasurer, an office he has held since 1899. A memorial resolution honoring Dr. Ezra T. Goble, Earlville, who died Feb. 23, 1938, was adopted during the meeting. Dr. Goble was a life member of the association who was admitted to membership in 1879. A life membership certificate was presented to Dr. Frank William Nickel, Eureka. Speakers at the meeting included Dr. Jacob Arnold Bargen, Rochester, Minn., who discussed 'Diagnostic Aids in the Management of Cancer of the Colon'.

**Health Officer Wanted**—Competitive civil service examinations will be held soon by the state department of health to fill the position of health officer of the Champaign-Urbana Public Health District at a beginning salary of \$4,500. Applications on special forms available on request must be on file in the offices of the department at Springfield not later than noon February 4. Applicants will be notified by letter as to the definite date of the examinations, which will be held in Chicago. To be eligible for examination, applicants must have graduated from a medical college of recognized standing, be eligible for a license to practice medicine and surgery in all its branches in Illinois and meet the qualifications set up for health officers by the Conference of State and Territorial Health Officers. Details and application forms may be obtained from Dr. Albert C. Baxter, acting state health director, Springfield.

## Chicago

**Dr Wangenstein to Give McArthur Lecture**—The fifteenth Lewis Linn McArthur Lecture of the Frank Billings Foundation of the Institute of Medicine of Chicago will be given by Dr Owen H Wangenstein, professor of surgery, University of Minnesota Medical School, Minneapolis, at the Palmer House January 27. The subject of the illustrated lecture will be 'The Genesis of Appendicitis in the Light of the Functional Behavior of the Vermiform Appendix.'

## INDIANA

**Secretaries' Conference**—The annual secretaries' conference of the Indiana State Medical Association will be held in the Green Room at the Indianapolis Athletic Club, Indianapolis, January 22. The program includes the following speakers:

- Dr Walter F Vest, Huntington, W. Va., 'The National Medical Situation';  
Dr George C Stevens, Indianapolis, 'Mental Hygiene Clinics';  
M. I. Hays and Frank A. Meriwether, Indianapolis, 'Farm Security Administration';  
Drs Donald A. Coyalt and Earl G. Montkomey, Muncie, 'Outline of Delaware-Blackford County Medical Society Plan for Postgraduate and Public Health Education';  
Dr Verne K. Harvey, Indianapolis, 'Indiana State Board of Health';  
J. K. Helsby, Kansas City, Mo., 'Hospital Insurance';  
Drs Norman M. Beatty and Joseph William Wright, Indianapolis, 'Legislative Problems';  
Dr James Harvey Crowder II, Sullivan, 'Some Observations on Plans to Establish District Health Units'.

**County Program for Medical and Lay Education**—The Delaware-Blackford County Medical Society, cooperating with the Muncie Academy of Medicine, has launched a program of medical graduate education and lay health education. The portion of the program designed for physicians has been developed along the lines of the Indiana Plan. Members of the society will be available for lectures to their own society as well as to others. The graduate aspect also includes weekly hospital ward rounds, clinical pathologic conferences, hospital staff meetings, surgical meetings and study club. In order that physicians may exercise a certain amount of control over the practical nurses in the vicinity, a practical nurses' training course and an American Red Cross course in home nursing have been included. Health exhibits, health education lectures, radio programs, high school talks, inter-high school debates and essay contests and the county fair health exhibit will be important instruments in carrying out the division of the program designed for lay education.

## LOUISIANA

**The Stanford E. Chaille Oration**—Dr Porter P. Vinson, professor of bronchoscopy, esophagoscopy and gastroscopy, Medical College of Virginia, Richmond, delivered the thirteenth annual Dr. Stanford E. Chaille Oration of the Orleans Parish Medical Society in New Orleans December 12 on 'Aid in the Early Diagnosis of Primary Bronchial Malignancy'.

**Society News**—The Ourchuta Parish Medical Society was addressed recently by Dr. Paul H. Herron, Monroe, on 'Diabetes in Infancy and Childhood'.—At a meeting of the Rapides Parish Medical Society in Alexandria November 7, Dr. Paul King Rand read a paper entitled 'The Painful Breast'.—Dr. Henry Theodore Simon, New Orleans, addressed the Tangipahoa Parish Medical Society November 10 on fractures of the extremities.

**Lectures on Medical Jurisprudence**—Lectures in medical jurisprudence have been added to the fourth year curriculum of the Louisiana State University Medical Center, New Orleans. The subjects include medical evidence and testimony, expert testimony, rights of medical witnesses, privileged communications, dying declarations, medicolegal postmortem examinations, malpractice, insanity, criminal acts determined by medical knowledge, and the legal relationships of the physician to his patients and to the public, according to the New York Times.

## MASSACHUSETTS

**District Meetings**—The Suffolk District Medical Society was addressed in Boston November 30, among others, by Drs. Grantley W. Taylor on 'Carcinoma of the Lip', Joe V. Meigs, 'Presacral Neurectomy for Dysmenorrhea', and Fuller Albright, 'In Vitro Dissolution of Kidney Stones'. A motion picture was shown by Dr. Marius N. Smith-Petersen on 'New Method of Arthroplasty of the Hip'.—At a meeting of the Norfolk District Medical Society in Boston November 29, Dr. Champ Lyons spoke on 'Clinical Immunology of Staphylococcus Infections'.

**Causes of Success and Failure**—Under a grant of the William T. Grant Foundation, a five year study into the causes of personal success and failure will be carried on at Harvard University, Cambridge. In charge of Dr. Arlie V. Bock, head of the department of hygiene, the study, to be undertaken by each student voluntarily, will deal with the heredity, constitution, family, school life and other elements pertaining to the makeup of the individual, according to the New York Times. The investigation proposes to analyze the forces that have produced normal young men. According to the report the term 'normal' means that combination of sentiments and physiologic factors which in toto is commonly interpreted as successful living. It is believed that through the study the students cooperating with the eight members of the staff who will work with Dr. Bock will make a memorable contribution to their own well being and to the process of education in its broadest sense. Facilities for the study have been provided in new offices adjacent to the hygiene building.

## MICHIGAN

**Society News**—Dr. Arnold Knapp, New York, discussed 'Chronic Glaucoma' before a joint meeting of the Detroit Ophthalmological and Otolaryngological Society and the Wayne County Medical Society January 6. The West Side Medical Society presented the program before the Wayne County Medical Society December 5, the speakers were Drs. Howard C. Walser on 'Asphyxia Neonatorum', Norbert M. Bittrich, 'Premedication and Spinal Anesthesia', and Robert L. Novak, 'Useful Drugs in Cardiac Therapy'. All are of Detroit.

**Dr. Ragsdale Superintendent of Butterworth Hospital**—Dr. Lucy V. Ragsdale, Boston, assistant superintendent of the Massachusetts General Hospital, Boston, has been appointed superintendent of the Butterworth Hospital, Grand Rapids, effective this month. He will succeed Dr. Norbert A. Wilhelm, who has been named superintendent of the Peter Bent Brigham Hospital, Boston. Dr. Ragsdale graduated at Harvard Medical School in 1924 and served for a time on the faculty of the University of Alabama School of Medicine. He was made assistant superintendent of the Massachusetts General Hospital in 1931.

**Advisory Committee on Health**—An advisory committee for the expansion of public health activities in Michigan was appointed by Governor Frank Murphy before expiration of his term according to the state medical journal, to act as the main steering committee to put into operation the plans advanced at the conference on public health in Lansing in September. Members of the committee include Dr. Edward J. O'Brien, Detroit; Henry F. Vaughan, Dr. P.H. Detroit; Dr. Cyrus C. Sturgis, Ann Arbor; William J. Scripps, Detroit; Louis J. Nims, Lansing; Paul de Kruif, Ph.D., Holland; and Dr. Henry A. Lucc, Detroit, chairman.

**Cancer Center**—A training center for the study of cancer will be established in Detroit under the auspices of the National Advisory Cancer Council, U. S. Public Health Service, Washington, D. C., newspapers report. Wayne University College of Medicine and Receiving, Women's and Grace hospitals will aid in establishing the center and give the courses to graduate physicians. The public health service will make appointments from nominations made by the faculty of the university. First year courses at Wayne will be directed by Dr. Edgar H. Norris, professor of pathology, and at Receiving Hospital by Dr. Osborne A. Brines. Second year courses will be conducted at Grace and Women's hospitals, while the third year will be devoted to general surgical experience at Receiving Hospital under supervision of Dr. Charles G. Johnston.

## MINNESOTA

**Personal**—Dr. Raymond J. Gully, formerly of the staff of the state hospital at St. Peter, has been appointed superintendent of a new state hospital in Cambridge.

**Society News**—Dr. Joseph D. Waller, Wilmont, was chosen president of the Southwestern Minnesota Medical Society at the annual meeting of the society and its women's auxiliary in Worthington recently. Dr. Rock Sleyser, Wauwatosa, Wis., President-Elect of the American Medical Association discussed 'Problems of the Day' before the Hennepin County Medical Society, Minneapolis, January 9.

## MISSOURI

**The Hodgen Lecture**—Dr. Frederick A. Collier, professor of surgery, University of Michigan Medical School, Ann Arbor, delivered the Hodgen Lecture of the St. Louis Surgical Society January 10, his subject was 'Studies on Altered Chemistry in Surgical Patients'.

**Personal**—Dr Ralf Hanks, superintendent of Fulton State Hospital, has been transferred to St Joseph State Hospital. Dr Orr Mullinax, superintendent of the latter, has been transferred to Nevada State Hospital, whose superintendent, Dr Thomas R Frazer, has been transferred to Fulton, according to *Modern Hospital*.

**Society News**—The resident staff of Firmin Desloge Hospital presented the program before the St Louis Medical Society at its meeting December 20, the speakers were Drs William H Vogt Jr on "Abdominal Pregnancy," case report with x-ray results, Kenneth R Andrews, Effects of Diet on Arterial and Venous Glucose Tolerance in Rheumatoid Arthritis," and John E Greutter Jr, Treatment of Gonococcal Arthritis with Typhoid Vaccine and Neoprontosil." Dr Albert Graeme Mitchell, Cincinnati, Ohio discussed 'Pediatric Aspects of Endocrinology' before the society December 13, under the auspices of the St Louis Pediatric Society.

## NEW JERSEY

**Care of Bedridden Indigents**—The Essex County Medical Society announces the formation of a volunteer list of physicians to care for bedridden indigents at home.

**Society News**—Dr Frank H Lahey, Boston, addressed the Camden County Medical Society, Camden, January 3, on 'Thyroid Disease'.—Dr Harrison S Martland, Newark addressed a stated meeting of the Academy of Medicine of Northern New Jersey, Newark, January 19 on "The Medical Examiner Looks at Obstetrics and Gynecology".—Dr David L Farley, Philadelphia, addressed the Gloucester County Medical Society, Woodbury, December 15 on 'Diagnosis in Fever of Obscure Origin'.—Dr Cary Eggleston New York, addressed the Hudson County Medical Society January 3 on 'The Use of Digitalis and Diuretics in Heart Disease'.—The Society of Surgeons of New Jersey will hold its annual meeting in Newark January 28.

## NEW MEXICO

**Society News**—Drs Ralph H Homan and Maurice P S Spearman, El Paso, Texas, addressed the Lea County Medical Society, Hobbs, recently on "Cardiac Neuroses" and "Peroral Endoscopy" respectively.—Drs Louis W Breck and Orville E Egbert, El Paso, Texas, addressed the Eddy County Medical Society recently at Artesia on "The Problems of State and Socialized Medicine".

## NEW YORK

**District Meeting**—The Second District Branch of the Medical Society of the State of New York held its annual meeting in Garden City November 16 with a program devoted to gastro-enterology. The speakers included Drs Albert F R Andresen, Brooklyn, on Medical Management of Peptic Ulcer, Benjamin W Seaman, Hempstead, "Surgical Indications in Diseases of the Gastroduodenal Tract," and Matthew Walzer, Brooklyn, "Gastrointestinal Allergy".

**Hospital News**—The Rochester General Hospital has established a tumor clinic to meet weekly. All known cases of malignant tumor in the outpatient department and in the ward service are to be reviewed and suggestions for treatment made by the clinic are to be followed. Suspected cases may be referred to the clinic for diagnosis and private cases may be reviewed by the clinic if the attending physician desires.—Tarrytown Hospital, Tarrytown received \$100,000 from the will of the late Edward Benedict Cobb retired lawyer of New York and Washington, who died at Pittsfield, Mass in November. It is reported that the bequest must be used for the endowment of beds in the maternity ward for charity patients.

### New York City

**New Foundation Established**—The Dazian Foundation for Medical Research was established through the will of the late Henry Dazian, who left \$1,325,288 to finance its work, according to the *New York Times*. It will operate by awarding funds for education of individuals and for research by individuals and institutions. It is to function for twenty-five years, after which its funds are to be apportioned among such hospitals and similar institutions as the directors may select. If the bequest is held invalid or subject to inheritance taxes, the funds are to be distributed to hospitals at once.

**Hospital Building Funds Approved**—Eight new dispensaries are to be begun immediately in connection with city hospitals with funds made available in the capital outlay budget of the city as finally approved. The hospitals are Coney Island, Cumberland and Kings County hospitals in

Brooklyn, Harlem and Bellevue in Manhattan, Morrisania and Lincoln in the Bronx, and Queens General Hospital in Jamaica, L I. Mayor La Guardia has persuaded Dr Sigismund S Goldwater, commissioner of hospitals, who recently announced his wish to retire, to remain in office another year to supervise these and other pending projects in the department.

**Cornell Withdraws from Welfare Hospital**—Cornell University Medical College has withdrawn its affiliation with Welfare Hospital, the city hospital for patients with chronic diseases on Welfare Island. Instead of the Cornell division there will now be an open division, to which members of the medical profession in general will be eligible. Dr Thomas A McGoldrick, Brooklyn, has been appointed attending physician and director of the medical service of the open division and Dr Condict W Cutler Jr, attending surgeon and director of the surgical service. Columbia University and New York University are affiliated with two other divisions. Their representatives are Drs Walter G Lough, attending physician, and William Barclay Parsons, attending surgeon, in the Columbia division and Drs Norman H Jolliffe, attending physician and William Howard Barber, attending surgeon, in the New York University division. Dr Willard C Rappleye, dean of Columbia University College of Physicians and Surgeons, and Dr Currier McEwen, dean of New York University College of Medicine, are ex officio members of the medical board.

## PENNSYLVANIA

**Society News**—D Roy McCullagh Ph D, Cleveland and Dr Lauric D Sargent Washington addressed the Washington County Medical Society January 11 on "Recent Advances in Endocrinology" and 'Pertinent Facts Concerning the Present Medical Situation' respectively.—The annual meeting of the Pennsylvania Tuberculosis Society will be held in Pittsburgh February 14-15.

### Philadelphia

**Personal**—Arno Viehoever, Ph D, research professor of biology at the Philadelphia College of Pharmacy and Science has received a leave of absence to serve as scientific adviser to the government of Siam. His special task will be to organize and direct a special research unit to explore, evaluate and utilize domestic curative and nutritional agents of the country.

**Medical Economics Night**—The meeting of the Philadelphia County Medical Society January 11 was designated 'Medical Economics Night'. The speakers were Drs Rosco G Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, on "Present Trends in Medical Economics" and Walter F Donaldson, Pittsburgh 'Medical Progress at Stake'.

**Society News**—Dr Walter Bauer Boston, delivered the twenty-first Nathan Lewis Hatfield Lecture of the College of Physicians of Philadelphia January 4 on 'Studies Pertaining to the Origin and Nature of Hypertrophic Arthritis'.—Dr Ralph Rhett Rathbone, Washington, D C, among others, addressed the Philadelphia Roentgen Ray Society January 5 on "Roentgen Diagnosis and Treatment of Sinusitis in Children".—Dr Theodore Cianfrani addressed the Obstetrical Society of Philadelphia January 5 on "A Series of Thirty-Five Cases of Primary Malignancy of the Ovary" and Dr Joseph A Ritter and Walter J Crocker, V M D on 'Macrocytic Anemia of Pregnancy and Anemia of the Newborn'.—Dr Henry C Bazett addressed the Philadelphia Rheumatism Society January 5 on 'Physiologic Effects of Heat'.

### Pittsburgh

**Society News**—Speakers at the meeting of the Allegheny County Medical Society December 20 were Drs Frank M Kern, on "Silicosis and Tuberculosis", William Glenn Srodes 'One Year of Insulin Shock Therapy for Schizophrenia', James H Rankin Jr "Metrazols Place in Psychiatric Treatment," and Verner B Callomon Treatment of Pneumonia with Type-Specific Immune Rabbit Serum.—Drs John B McMurray, Washington, and James H McCready addressed the Pittsburgh Otological Society December 5 on sinusitis.

**New Dean Appointed**—Dr William S McEllroy, professor of physiologic chemistry, University of Pittsburgh School of Medicine has been appointed dean to succeed the late Dr Raleigh Russell Huggins. Dr McEllroy has been acting dean since February 1938. He is a native of Pittsburgh and graduated from the university medical school in 1916. He was made an instructor in the same year he graduated and became assistant professor in 1920 and professor in 1921. He has conducted research on blood pigments, protein and iron metabolism, kidney functions determining of reducing sugars and a emias.

## VERMONT

**University News**—Harold B. Pierce, Ph.D., professor of biochemistry, University of Vermont School of Medicine, Burlington, has been appointed head of the department of biochemistry and acting head of the department of pharmacology.

**Governor Discusses Health Insurance**—In his message to the legislature January 5 Governor Aiken had the following to say concerning medical care in the state:

We recognize that many people who should be getting medical care or hospitalization are not now receiving it. It is also an accepted fact that much improvement could be brought about through cooperative efforts by communities or possibly on a statewide basis.

There may be federal legislation concerning health insurance. Vermont wants no part in any plan which would permit political selection of doctors or the direction of their activities by the government. But we ought to be ready to cooperate either among ourselves with the people of other states or with the federal government on any plan providing for cooperative and voluntary efforts to promote better health among our citizens.

Hospital doctors and laymen in Vermont are all working toward this end. It may be that some plan will be devised before this legislature adjourns that will appear practicable and will permit the broadening of our present sporadic efforts to a statewide basis. If such a plan is devised and legislation appears necessary to make it effective, I hope such legislation will be enacted.

## WISCONSIN

**Society News**—Dr. Charles R. Austrian, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, gave the Juppitt Memorial Lecture of the Medical Society of Milwaukee County January 13 on "Chronic Nontuberculous Pulmonary Infections."—Dr. William A. Deerbake, superintendent of the Central State Hospital for the Insane, Waupun, addressed the Dodge County Medical Society December 1 at a meeting at the hospital on "Shock treatment of dementia praecox." Dr. Campbell C. Edmondson, Waukesha, addressed the society December 29 on "rheumatism."—At a meeting of the Green Lake Waushara County Medical Society in Berlin December 19 the speakers were Dr. William J. Blockwenn, Madison, on diagnosis and treatment of head injuries and Harry R. Foerster, Milwaukee, on industrial dermatoses.—The Outagamie County Medical Society met with the Outagamie County Dental Society December 3 when Isaac Schour, D.D.S., Chicago, gave an address on "Calcium Metabolism and Teeth."—Speakers before the Racine County Medical Society, Racine, December 15 were Dr. John F. Bennett, Burlington, on Mesenteric Phlebotomy and David J. Anshel, Milwaukee, "Posture in Childhood" and Mr. J. C. Gamroth, director of the compensation division of the Works Progress Administration, Madison, "WPA as It Affects Doctors in This State."

## GENERAL

**New Members of Cancer Council**—Dr. James B. Murphy, chief of the cancer research division of the Rockefeller Institute for Medical Research, New York, and Mont R. Reid, professor of surgery, University of Cincinnati College of Medicine, have been appointed members of the National Advisory Cancer Council for three year terms. They succeed Dr. Francis Carter Wood and James Ewing, New York.

**New Special Society**—The Southwestern Society of Eye, Ear, Nose and Throat Specialists was organized Oct. 27, 1938, during the annual meeting of the Southwestern Medical Association in El Paso. Officers elected were Drs. Percy Dale Biddle, Tucson, Ariz., president, William C. Burton, Santa Fe, N. M., vice president, and Maurice P. S. Spearman, El Paso, secretary. Meetings will be held annually during the sessions of the Southwestern Medical Association.

**South Atlantic Obstetricians and Gynecologists to Meet**—The South Atlantic Association of Obstetricians and Gynecologists will hold its annual meeting February 10-11 in Charleston, S. C. The guest speakers will be Drs. Edward H. Richardson, Baltimore, on "Surgical Management of Uterine Prolapse and Associated Benign Pathology" and George W. Kosmak, New York, "What Do We Mean by Conservatism in Obstetrics?" Dr. James R. McCord, Atlanta, Ga., is president of the association and Dr. Robert A. Ross, Durham, N. C., is secretary.

**Offer Gold Medal in Ophthalmology**—The University of Buffalo offers again its annual gold medal for a work on an ophthalmologic subject, according to an announcement. Any physician is eligible to compete for the medal and there are no restrictions as to length of the work. Contributions should be in the hands of the committee before May of each year, as the award is made in June. The committee is composed of Drs. Frederick H. Verhoeff, Boston, Arthur J.

Bedell, Albany, N. Y., and Harold W. Cowper, Buffalo. For details address Dr. Cowper at 543 Franklin Street, Buffalo, N. Y.

**Special Society Elections**—Dr. Bernard H. Nichols, Cleveland, was elected president of the Radiological Society of North America at its annual meeting in Pittsburgh Nov. 28-Dec. 2, 1938. Drs. William Walter Wasson, Denver, James J. Clark, Atlanta, and Manuel F. Madrazo, Mexico D. F., were elected vice presidents. Dr. Donald S. Childs, Syracuse, N. Y., was reelected secretary.—Dr. Walter H. Nadler, Chicago, was elected president of the Central Society for Clinical Research at its eleventh annual meeting in Chicago Nov. 4-5, 1938. Dr. Charles A. Dorn, Columbus, Ohio, was chosen vice president and Dr. Lawrence D. Thompson, St. Louis, was reelected secretary-treasurer. The next annual session will be at the Drake Hotel, Chicago, November 3-4.

**Theobald Smith Award**—Dr. Charles F. Code, Rochester, Minn., received the Theobald Smith Medal and cash prize of \$1,000 awarded by the medical section of the American Association for the Advancement of Science at its midwinter meeting in Richmond, Va. Dr. Code was honored for research showing that histamine is present in increased amounts in the white blood cells of persons suffering from hay fever, asthma and some other allergic diseases. He is 28 years old and graduated from the University of Manitoba Faculty of Medicine, Winnipeg, in 1934. The award was established in 1935 by Eli Lilly & Co., Indianapolis, to be presented to an investigator under 35 years of age for demonstrated research in the field of the medical sciences taking into consideration independence of thought and originality.

**Infantile Paralysis Foundation**—Preceding the annual birthday balls on President Roosevelt's birthday January 30 by which funds are raised to fight infantile paralysis, a nationwide campaign for funds called "The March of Dimes" is being carried out. The slogan is "Give a Dime and Wear a Button" and citizens are asked to contribute 10 cents and wear a button publicizing the campaign. Cards holding ten dimes are also being distributed; recipients are asked to fill them and send them to the President. Among other phases of the campaign is a series of sports events sponsored by the sports council of the Committee for the Celebration of the President's Birthday. Grantland Rice is chairman of this activity to raise funds. This year the funds will be divided in half: one part to remain in the localities where the money is raised and the other half to be sent to the National Foundation for Infantile Paralysis for support of research and new treatment centers. The foundation has just announced grants of \$140,990 to universities and hospitals for research the following grants were made:

Yale University School of Medicine	New Haven Conn.	\$6,500
Long Island College of Medicine	Brooklyn N. Y.	\$15,000
University of California Medical School	San Francisco	\$5,000
University of Southern California School of Medicine	Los Angeles	\$10,000
Stanford University School of Medicine	San Francisco	\$12,000
University of Michigan Medical School	Ann Arbor	\$2,000
University of Wisconsin Medical School	Madison	\$3,300
Ohio State University College of Medicine	Columbus	\$3,000
Western Reserve University School of Medicine	Cleveland	\$4,800
Washington University School of Medicine	St. Louis	\$6,800
Cornell University Hospital	Ithaca N. Y.	\$7,500

In addition the following hospitals received grants for prevention and treatment of after-effects:

Orthopedic Hospital School	Los Angeles	\$7,800
Children's Hospital School	Baltimore	\$7,500
St. John's Hospital	Springfield Ill.	\$2,500
Michael Reese Hospital	Chicago	\$4,600
James Whitcomb Riley Hospital	Indianapolis	\$6,000
Children's Hospital	Martin Texas	\$2,500
New York Hospital	New York	\$4,580
University Hospitals	Iowa City	\$8,500
Hospital for Joint Diseases	New York	separate grants in different departments \$4,250, \$3,800, \$5,500 and \$5,500
Scottish Rite Hospital	Dallas Texas	\$10,000

Dr. Thomas M. Rivers, New York, is chairman of the foundation's advisory committee on scientific research, which approved all grants for research. Dr. Philip Lewin, Chicago, is chairman of the committee on prevention and treatment of after-effects, which approved all grants for that purpose.

**Plan for Examinations in Ophthalmology**—The American Board of Ophthalmology announces a change in its methods of examining candidates. Examinations are to be divided into two parts, written and oral. Candidates whose applications are accepted will be required to pass a written examination, which will be held simultaneously in various cities about sixty days prior to the date of the oral examination. The written examination will include all the subjects previously covered by the practical and oral examinations. Oral exami-

nations will be held at the time and place of the meeting of the American Medical Association and of the American Academy of Ophthalmology and Otolaryngology and occasionally in connection with other important medical meetings. The oral examination will cover external diseases, ophthalmoscopy, pathology, refraction, ocular motility and practical surgery. Only those who have passed the written examination and who have presented satisfactory case reports will be permitted to appear for the oral examination. Written examinations will be held March 15 and August 5, oral examinations will be held in St. Louis May 15 and in Chicago October 6. Applications for the March 15 examination must be filed before February 15 with the secretary, Dr. John Green, 6830 Waterman Avenue, St. Louis, Mo.

### CANADA

**Society News**—Dr. Karl Haig, Vancouver, B. C., addressed the Vancouver Medical Association December 6 on "Diagnosis of Congenital Dislocations of the Hip, with Treatment of Those Which Are Reducible"—Dr. Reginald Fitz Boston, addressed the Academy of Medicine of Toronto at its stated meeting December 6 on "The Periodic Health Examination as a Method of Clinical Investigation."

**Laboratories for Electro-Encephalography**—New laboratories for research on electro-encephalography were to be opened at the Montreal Neurological Institute early this month according to *Science*. Herbert H. Jasper, Ph.D., recently assistant professor of psychology at Brown University and director of the neurophysiologic laboratories and the psychologic clinic at Bradley Home, Providence, R. I., will be in charge of the work, which will be financed by a grant from the Rockefeller Foundation. Epilepsy and dementia will be the subjects of special study. Since the institute was opened in 1934 extensive research on epilepsy has been carried on by Dr. Wilder Penfield, director of the institute and professor of neurology and neurosurgery at McGill University Faculty of Medicine. Citizens of Montreal contributed funds for an extension of the institute building for the new laboratories.

## Government Services

### Division for Research on Quinine Derivatives

The National Advisory Health Council approved the establishment of a division in the National Institute of Health, U. S. Public Health Service, to carry on research into possible new uses of quinine derivatives. It is reported. The new division will also study the possibilities of raising the plant on American soil. At the present time most of the output of quinine comes from the East Indian colonies of the Netherlands. Lyndon F. Small, Ph.D., research associate in organic chemistry, University of Virginia, Charlottesville, has been appointed to be in charge of the new unit, effective next summer, it was stated.

### Examination for Medical Corps of the Navy

An examination of candidates for appointment as Lieutenant (junior grade) in the Medical Corps of the Navy will be held at all naval hospitals in the United States and at the Naval Medical School, Washington, D. C., beginning May 8.

Candidates for admission to this examination must be citizens of the United States between the ages of 21 and 32 years at time of appointment, graduates of class A medical schools and must have completed an internship of one year in a hospital accredited for interns by the American Medical Association and the American College of Surgeons.

Those who are interested should write the Surgeon General, U. S. Navy Bureau of Medicine and Surgery, Navy Department, Washington, D. C., for further information with regard to the examination and the procedure to follow for them to appear before one of the examining boards.

Graduates of class A medical schools who have completed an internship in a civilian hospital and who successfully pass the competitive professional examination and the physical examination will be commissioned as assistant surgeons with the rank of Lieutenant (junior grade) and assigned to the Naval Medical School, Washington, D. C., for a graduate course prior to assignment to sea or foreign shore duty. Formal applications to take the examination should be forwarded in duplicate to the Bureau of Medicine and Surgery of the

Navy, Washington, D. C., at least a month in advance of the examination. The application should be accompanied by (a) letters or certificates from two or more persons of good repute, testifying from personal knowledge to good habits and moral character, (b) satisfactory evidence as to citizenship and age, (c) a certificate of graduation in medicine and a certificate of internship from a civilian hospital (do not submit diplomas), (d) recent photograph (preferably 5 by 6 inches) and (e) if the candidate has had special educational or professional advantages, a certificate to this effect, signed by the proper authority, should be forwarded.

If the credentials are satisfactory the Bureau of Medicine and Surgery will recommend that a permit be issued to the candidate to appear before an examining board nearest his medical school or place of residence. On accepting appointment as assistant surgeon with rank of Lieutenant (junior grade), the officer receives compensation of \$2,699 a year if he has no dependents and \$3,158 a year if he has dependents. There is an allowance of 8 cents per mile for travel to his first station of duty. No allowance is made for expenses of candidates appearing for examination. After officers have been in the service long enough to assure the Bureau of Medicine and Surgery of their remaining in the service and have become thoroughly familiar with the naval officer's duties and have demonstrated their professional qualifications, special courses may be authorized at various institutions to enable the officer to specialize along lines of his choice. Medical officers are eligible for promotion in the navy under such provision of law as may be in effect at the time. Naval officers are retired from active service at the age of 64 years and then receive annual pay for life amounting to three fourths of the base pay of their grade at the time of retirement.

### Examination for Appointment to U. S. Public Health Service

An examination to establish eligibility for appointment in the commissioned corps of the United States Public Health Service in the grade of assistant surgeon (medical only) is hereby announced to be held on the dates mentioned below. Applicants must not have passed their thirty-second birthday on the date the examination is taken, must be citizens of the United States, graduates of a class A medical college and must have completed or will complete by July 1, next, at least one year of internship or its equivalent.

The compensation of officers in the grade of assistant surgeon, both regular and reserve corps, is \$3,158 per annum with dependents and \$2,699 per annum without dependents.

The board of examiners will be in the following places at the time specified for the purpose of making the necessary physical examinations and conducting certain other portions of the examination:

U. S. Marine Hospital Boston 9 a. m. January 31  
U. S. Marine Hospital Stapleton N. Y. 9 a. m. February 1  
U. S. P. H. S. Hospital Lexington Ky. 9 a. m. February 9  
U. S. Marine Hospital New Orleans 9 a. m. February 14  
U. S. Marine Hospital St. Louis 2 p. m. February 27  
Colorado Psychopathic Hospital Denver 9 a. m. March 1  
U. S. P. H. S. Relief Station Los Angeles 9 a. m. March 3  
U. S. Marine Hospital San Francisco 9 a. m. March 6  
U. S. Marine Hospital Seattle 9 a. m. March 10  
Indian Field Service Office 161 Federal Bldg. Minneapolis 9 a. m. March 14  
U. S. Marine Hospital Chicago 9 a. m. March 16  
U. S. Marine Hospital Cleveland 9 a. m. March 18  
U. S. P. H. S. Building Washington D. C. 9 a. m. March 27

Applicants desiring to take this examination should make arrangements to appear before the board at any of the places mentioned at the time and on the dates specified.

Those who complete the physical examination and certain other portions of the examination will be permitted to participate later in the written portion of the examination beginning March 30 either at the place where the physical examination is conducted or at some other nearer point, or candidates may elect to come to Washington, D. C., March 27 to take the entire examination. The written and clinical portions of the examination will consume about three days. Any travel expenses to be incurred must be defrayed by the applicant.

If time will permit, applicants may obtain formal application blanks by writing to the Surgeon General, U. S. Public Health Service, Washington, D. C. These forms may be filled out and delivered personally to the board of examiners or blanks may be had from the board at the time the applicant appears for examination. Applicants will be required to present their diplomas to the board.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Dec 21, 1938

#### Research on the Anemias

The most important work on pernicious and other anemias done in the last few years in this country has been produced by Dr John F Wilkinson, director of the department of clinical investigations and research of the University of Manchester. His report for 1937-1938, which has just been published shows important advances

#### ADRENAL CORTICAL EXTRACT IN ADDISON'S DISEASE

Last year the department completed a research at the request of the Medical Research Council on the effect of adrenal cortex extract in the treatment of Addison's disease. The patients then successfully treated have now remained alive and well for a further twelve months under much decreased or minimal doses of the extracts with marked improvement in general health. The longest surviving patient has now been under observation for four and one half years. At the council's request a further investigation of the new synthetic adrenal cortex extract—desoxycorticosterone acetate—doses of which are much less than those of the extracts previously used, has been begun. Three patients have been treated with these small doses and the results have been most encouraging.

#### ETIOLOGY AND TREATMENT OF THE ANEMIAS

Investigations have been continued on the etiology and treatment of pernicious anemia, achrestic anemia (first described in 1935 by Wilkinson and Israels under this name), hemolytic anemia and hypochromic anemias. The treatment of hypochromic microcytic anemias has been subject to further inquiries, but so far satisfactory preparations of iron suitable for parenteral administration have not been found, massive doses of ferrous salts orally is still the best treatment.

#### THE TREATMENT OF PERNICIOUS ANEMIA

Work has been done on the improvement of liver and stomach preparations for the treatment of pernicious anemia. Potent extracts containing very small quantities of solids have been used but there appears to be evidence that accessory factors may be necessary for a complete return of the patients to normal. Thus it has been noted that the highly purified liver extracts may produce only reticulocytosis and partial or slow improvement in the red cells and hemoglobin percentage without the complete and rapid return to normal that follows the use of less highly purified liver extracts. Much further work is required to elucidate the nature of these possible accessory factors, but it is improbable that they are vitamins B and C. By incubation experiments with stomach tissue and beef muscle and administration of the products to patients suffering from pernicious anemia it has been shown, by the curative effects, that hemopoietin is present in the normal human stomach but absent from the stomachs of patients suffering from pernicious anemia both in remission and in relapse. This confirms previous work with gastric juice. The intrinsic activity of livers from animals has been investigated, in general, mammalian and fish livers proved active but reptilian (giant monitor, alligator and others) and different snake livers were inactive. The significance of these experiments is under consideration.

#### A STUDY OF BONE MARROW OBTAINED BY STERNAL BIOPSY

The assistant director, Dr M C G Israels, has been chiefly engaged in a study of bone marrow obtained by sternal biopsy for tissue culture experiments. Marrow cells from patients with leukemia have been grown in a medium containing human placental extract. A photomicrographic apparatus has been used for recording the results. The morphology of bone marrow

in blood diseases has been closely studied and there is no doubt that valuable diagnostic information can be so obtained. The researches have greatly aided in the classification and therefore in the treatment of patients with anomalous anemias. Some of these appear to be due to disturbances of erythropoiesis and others to be related to the leukemias. (The results suggest that pernicious and allied anemias are alone characterized by the appearance of megakaryoblasts in the bone marrow, other disturbances involve the normoblastic series of cells.) Dr Israels has been elected to the Foulerton Research Fellowship of the Royal Society and therefore has resigned his appointment as assistant director.

#### Medical Services in Air Raids

Gradually the preparations made to render medical services to civilians during air raids should the threat of war have materialized in the recent crisis are being disclosed. The government plan was a regional organization for dealing with casualties on the basis of first making available beds in existing institutions and then expanding these institutions by satellite annexes. For personnel there was a register of physicians and of nurses. Some months ago the British Medical Association on the invitation of the Committee of Imperial Defense, compiled a register of the medical personnel available in war. This register now included 95 per cent of the physicians in the country. If war had come, they would have been directed to the places where the needs were greatest. But clearly the best place for a physician on the outbreak of war was with his own patients. There was bound to be a heavy strain on his practice particularly in areas into which the populations from crowded places were to be evacuated. In any case the most obvious air raid post was the physician's office. The problem of coordinating the claims of the fighting services on the physicians with those of the civilian population was being discussed.

A survey of the whole hospital accommodation of England and Wales had been made with a view to expansion. It covered 3,000 hospitals and institutions and just over 40,000 beds. Hospital officers were sent to every region with instructions to free as many hospital facilities as possible in the more congested areas so that in case of emergency more elaborate schemes could be evolved. At the outbreak of war 150,000 beds would have been available for air raid casualties and at the end of a fortnight another 100,000. These did not include the beds in London, for which there was special organization. A circular had been sent to every hospital stating that the personnel must be ready to clear as many beds as possible on receiving warning from the government and must prepare schemes for expansion in case of need. There was the hospital officer on the spot ready to assist in working out scheme. Arrangements were made for first aid posts, each staffed by a physician. The government ordered 50,000 bedsteads and mattresses, 15,000 blankets and 9,000 stretchers.

#### TRANSPORT SCHEMES

Transport was a vital question in clearing the London hospitals. In addition to the patients who were to be sent home to make room for casualties, between 3,000 and 4,000 patients in thirty-four of the larger general hospitals which would be most valuable to the casualty organization, were to be removed on stretchers to smaller towns about fifty miles distant. Three hundred omnibuses were to be converted at from twelve to twenty-four hours' notice into ambulances, each capable of taking eleven stretchers. Fitters were standing by to do the work. Arrangements were also made to assemble twenty-one ambulance trains at selected stations (not the terminals), and the St John Ambulance Brigade arranged to provide stretcher bearers to carry the patients from the omnibuses to the trains. Detailed plans were worked out with the transport board and the railway companies to insure synchronization, and Septem

ber 24 the necessary stretchers were distributed to each evacuating hospital. From that point the hospital evacuation of London could have been put into force at twelve hours' notice. The government is now making a comprehensive house to house survey of practically all rural England as a first step in the evacuation of children from cities in war time. An evacuation division of the ministry of health has been constituted. Plans for the evacuation of adults will be made later.

### The Jubilee of the British Journal of Dermatology

The only British journal devoted to dermatology has celebrated its jubilee by a special number devoted to a survey of its work during the past fifty years, which means a survey of British dermatology during that period. It is strange that, although the foundations of modern dermatology were laid in London at the beginning of the nineteenth century by William and Bateman, there was no society devoted to it until the Dermatological Society of London was founded in 1882 by Stowers and Sangster and not until six years later was a special periodical, the *British Journal of Dermatology and Syphilis*, founded. Yet corresponding periodicals had been published on the European continent and in America for many years. In "A Retrospect" J. M. H. Macleod tells how the journal was founded by Morris and Brooke and at first issued under their combined editorship at a time when dermatology as a specialty received scant and grudging recognition. In London only a few of the teaching hospitals had dermatologists on their staffs, and their dermatologic departments were staffed by young physicians and surgeons whose interest in them was apt to be ephemeral and who regarded them only as stepping stones. A few physicians—Pye-Smith, Mackenzie, Payne, Omerod and Galloway—made important contributions to dermatology though engaged in the practice of general medicine. Excellent portraits are given of the successive editors of the journal. Sir Ernest Graham-Little gives interesting sketches of celebrated British dermatologists of the past fifty years. He describes that greatest of clinicians, Sir Jonathan Hutchinson, as a fascinating teacher attracting crowded audiences to his lectures and demonstrations which were 'better than a play' and ranging, as his experience allowed him to do, over multifarious subjects. Thus in a hospital lecture on 'Fairy Rings and Allied Phenomena' he passed from the rings of fungi in the fields to ringworm and herpes. In making syndromes and discerning connections between diseases not obviously connected he was a past master.

### The Recognition of Chiropodists

After some opposition, chiropodists were recognized by the British Medical Association as medical auxiliaries for the treatment of corns and bunions. The chiropodists have now consolidated their position by forming a Chiropody Group Council as the qualifying body in chiropody to the Board of Registration of Medical Auxiliaries. An immediate outcome of the work of the council will be the preparation of an official register of chiropodists. This will be circulated to physicians, hospitals and municipalities and other bodies. The practice of chiropody will be entirely directed and controlled by the council.

### Bill for the Use of Blood Tests in Affiliation Cases

In this country the courts cannot order blood tests in affiliation proceedings. As these cannot prove paternity but only nonpaternity, the woman has nothing to gain in allowing them. A bill has been introduced in the House of Lords giving the court power, at the request of either party, to require a woman who brings affiliation proceedings to undergo blood tests to ascertain whether the defendant can be excluded from the paternity of her child. If she refuses, her application will be refused. If she consents the court shall nominate an approved person to carry out tests on her blood, the blood of her child and that of the defendant.

### Preoperative Serotherapy in Appendicitis

At the November 29 meeting of the Académie de médecine, Professor Weinberg, bacteriologist at the Pasteur Institute, read a paper advocating the use of an antigangrene serum as a preoperative measure in cases of appendicitis, especially if complicated by peritonitis. Such excellent results followed the use of a polyvalent antigangrene serum in the French army during the World War that the author of the paper recommended its use in serious cases of appendicitis. Prof. Paul Delbet in 1920 was the first to follow this suggestion. Since then 441 cases of perforated and nonperforated gangrenous appendicitis have been treated with a serum containing the polyvalent antigangrene serums, the anti-colon bacillus serum and a complementary serum which aims to combat other secondary bacteria, such as the enterococcus, streptococcus, *B. ramosus*, *B. funduliformis*, *B. fusiformis* and *Staphylococcus parvulus*, which play an important part in the evolution of a gangrenous appendicitis. This antiperitonitis serum has given excellent results in France, in Poland, in Russia and at the Mayo Clinic.

Professor Weinberg was of the opinion that the mixed serum acts as a specific and cited eight cases in which operative intervention could not be carried out for "moral or material reasons" with recovery following the use of the mixture of antigangrenous and anti-colon bacillary serum. He said that whenever it was impossible to perform an emergency operation the patient should be given the benefit of serotherapy. A large dose, from 80 to 100 cc of the antiperitonitis serum diluted with from 200 to 500 cc of physiologic solution of sodium chloride, ought to be injected immediately by the intramuscular or subcutaneous route. The injection should be repeated two or three times within the first twenty-four hours. As soon as the acute symptoms subside, operation is indicated.

In the discussion, Professor Vincent said that he had found the mixed serum very efficacious in the treatment of cases of gangrenous appendicitis, especially if complicated by peritonitis. Appendectomy, however, should be performed whenever possible.

Prof. Pierre Duval warned against a false interpretation of the recommendation of Professor Weinberg to use the mixed serum in cases in which operation could not be performed for "moral or material reasons." In acute appendicitis, especially the gangrenous form, operation should be performed as soon as possible.

Prof. A. Gosset said that every effort must be made by the profession to eliminate such 'moral or material reasons' for delay in performing operations in acute cases.

### Inhalations of Oxygen and Carbon Dioxide in Pneumonia

Two naval surgeons, Hederer and Andre, read a paper at the November 15 meeting of the Académie de médecine of Paris in which they reported their observations on the use of various mixtures, such as 5 per cent carbon dioxide and 95 per cent oxygen in the treatment of acute pulmonary conditions at the Toulon naval hospital. Their conclusions were that the Henderson mixture (5 per cent carbon dioxide and 95 per cent oxygen), like oxygen, increases the oxygen content of the hemoglobin. Five per cent carbon dioxide will not do this. Both of these, as the result of stimulation of the respiratory center, increase the dyspnea to such an extent as to exhaust the patient. Hence this method of treatment is not to be recommended at present in the treatment of any acute pulmonary condition of bacterial origin. In pulmonary conditions of chemical origin the use of Henderson mixture is distinctly contraindicated. In the latter group of cases the

experience acquired during the World War and more recent experimental studies have demonstrated the value of absolute rest with reduction of pulmonary excursions to the minimum. The administration of a carbon dioxide oxygen mixture to such patients, by increasing the respiratory rate, favors the extension of the congestion and edema at all stages of the intoxication by gases such as those now employed in warfare. Only oxygen in pure form should be given in such cases.

### Well Known Quack and Assistant Are Fined

A foreigner who looks over the advertising columns of French newspapers will be astonished at the space occupied by quacks of all types. One of the most successful charlatans is Dr. Vidal, who claims to be able to diagnose and cure any form of disease by pressure exerted on the sympathetic nerve endings in the nasal mucous membrane. This super quack has numerous offices in Paris and larger cities all over France. In spite of every attempt to check his activities by the medical organizations, the leniency of the courts permits him to escape with a fine which is out of all proportion to his receipts. An exception to this leniency has just been reported in a case in which Dr. Vidal had employed a foreign physician who did not have a French diploma. Dr. Vidal was fined 5,000 francs and the assistant 1,000 francs but this will not deter the former from continuing to exploit the credulity of the public.

### Influence of Sulfanilamide on Experimental Tetanus

A possible extension of the application of chemotherapy to acute infections such as tetanus formed the subject of a paper read by Dr. R. J. Mayer at the Académie de médecine of Paris. It is comparatively easy to produce tetanus in mice by the subcutaneous injection of earth containing the bacilli. Of the two drugs which were employed in his experiments sulfanilamide and alpha para amino-phenyl-sulfonamide, the former is four times more toxic than the latter but its activity toward all bacteria except streptococci is less marked. Of thirty control animals, only one, or 3.3 per cent, lived after the injection of earth containing tetanus bacilli, whereas of ninety-five mice which were given one of these drugs forty one or 43 per cent, survived. The author expressed the opinion that in the future chemotherapy may play an important part in the prevention and treatment of tetanus.

### Anniversary of Ophthalmic Society

The Société d'ophtalmologie of Paris celebrated the fiftieth anniversary of its foundation November 20. The program included a paper on encephalomalacia by Professor Lhermitte, a review of the fifty years' work of the society by Dr. Magitot, the secretary, and a paper on retinopathy in hypertension by Dr. Dubois-Poulsen. In the secretary's report, mention was made of such distinguished ophthalmologists as Galewowski, de Wecker, Patin and Landolt, who had been members. Representatives of the Swiss, Belgian and other foreign societies were present at the meeting and praised the work of the Paris organization since its foundation fifty years ago.

### Honorary Degrees Conferred on Biochemists

At the opening session of the University of Paris, held at the Sorbonne November 5, honorary degrees were conferred on Professors Karrer of Switzerland, Szent-Györgyi of Hungary and Sorensen of Denmark. The first two have received the Nobel prize. Professor Karrer is head of the department of chemistry at the University of Zurich. His work on the chemical composition of the colors of flowers and vegetables, as well as his research on the synthesis of vitamin E, has attracted the attention of the scientific world. Professor Szent-Györgyi is head of the department of medical chemistry at the University of Szeged, Hungary, and is especially known for his work on ascorbic acid, which he demonstrated as being

identical with the antiscorbutic vitamin. Professor Sorensen is director of the Carlsberg research laboratory at Copenhagen and has made important contributions in the field of biochemistry.

### Program of 1939 French Tuberculosis Congress

The ninth annual meeting of the French Tuberculosis Society will be held at Lille, in northern France, April 11-13. The program includes discussions on the specific characters and role of various types of tubercle bacilli other than the human type in tuberculous infection in man, puriform and purulent pleural exudates following artificial pneumothorax and their treatment, and preventive measures against tuberculosis by systematic examination of the population.

### Opposition to Compulsory Antidiphtheria Vaccination

France is divided into ninety departments or counties, in each of which there is a local governing body termed the general council. At a recent meeting of such a council at Lyons which is located in one of the most densely populated departments (Rhône), the mayor, Mr. Herriot, stated that there is a noteworthy increase in the number of cases of diphtheria in spite of the use of diphtheria toxoid vaccination. In another department, Aude, several physicians protested against accepting a subsidy for compulsory vaccination against diphtheria on the ground that deaths had followed the use of the vaccine.

### Honorary Degree Conferred on American Surgeon

At the opening exercises of the University of Strasbourg, November 5, an honorary degree was conferred on Dr. Elliott C. Culler, professor of surgery at Harvard University, in recognition of his important contributions to surgery.

### Diarrheas of Nurslings

Professor Besenau Berlin, ordinaris in pediatrics, in discussing the pathogenesis and treatment of the diarrheas of nurslings before the Berlin Medical Society, said that as a rule diarrhea of nurslings is not caused by the nutriment. Artificial feeding may, however, lead to a predisposition to diarrhea. The greater part of cases of diarrhea in nurslings are based on infection. The colon bacteria are of paramount importance. The very young infant harbors no bacteria of this group. During the first weeks of life the large intestine first adapts itself to these bacteria. The sole physiologic flora of the large intestine of the nursling is *Lactobacillus bifidus*, which usually does not permit the advance of a *B. coli* flora. The mechanism of the action of *B. coli* consists in the destruction of the carbohydrate. These fermentative processes are physiologic in the large intestine but pathologic in the small intestine. The acid products of fermentation stimulate peristalsis. It is the living micro-organisms that are injurious, not their products of decomposition. Premature infants are physiologically dysergic since in them *Lactobacillus bifidus* is not developed at the proper time. The therapy of diarrheas of nurslings must have as its objective elimination of pathologic flora from the gastroenteric tract. Starvation treatment removes the products of decomposition and therewith the nutrient medium of saprophytes. Feeding of gruel soups acts similarly to starvation, besides, the mealy substances exert a special favorable influence which cannot be explained. Feedings with buttermilk, in which *B. coli* cannot be cultured, represent a further therapeutic measure. In addition, the effort must be made to produce the proper flora by means of breast milk. It is extremely difficult, of course, to eliminate *B. coli* by culture of *Lactobacillus bifidus*. Furthermore albumin milk has a noticeable

influence, it leads to formation of a quite water-deficient stool containing calcium soaps, in the large intestine, the colon bacilli can thrive but poorly in this medium. After feeding with whey the B coli flora disappears almost immediately. Bessau recommends that the treatment of diarrheas of nurslings begin with a period during which the infant receives only tea, subsequently a mixture of about one half whey, one half water and 8 per cent rice water together with sodium citrate is given. The worth of this dietary has been verified in practice.

#### The Prevalence of Brucellosis

In the years 1936 and 1937 there were 597 and 586 cases, respectively, of infection with *Brucella abortus* Bang officially reported, which were serologically authenticated. In the table are set forth the number of such cases reported each year during the last decade.

It will be seen that during the first four years the number of reported cases declined, only to rise again in subsequent years but without attaining the peak of 1929-1930. The male sex was preponderantly affected. 1936, 462 males and 135 females, 1937, 431 males and 155 females. As in earlier years, most of the patients were men in their active years, whereas few old persons and children were affected. Each appearance of the infection was an isolated case. Transmissions from

*Number of Cases of Infection with Brucella Abortus*

Years	Cases Reported
1929-1930 (Oct 1 to Sept 30)	626
1930-1931	520
1931-1932	498
1932-1933	483
1933-1934	530
1934-1935	513
1935 (Oct 1 to Dec 31)	146
1936 (Jan 1 to Dec 31)	597
1937 (Jan 1 to Dec 31)	586

person to person were nowhere determined. In 1936 one case of abortion as a sequel of brucellosis was reported. In the same year there were five fatalities ascribable to the disease, in 1937 there were three such fatalities. Diseases with which brucellosis in its critical stages was confounded were cholecystitis, tuberculosis, cancer, pernicious anemia, articular rheumatism, cystopyelitis and typhoid. In two cases Widal reactions were positive for brucellosis and typhoid. *Brucella abortus* was cultured from the blood in forty-four cases during 1936 and in thirty-nine cases during 1937. In each instance culture was obtained from puncture material and from pus. With regard to sources of infection, contact with infected cattle and ingestion of raw milk and dairy products were far the most notable. Besides, during 1936 four cases of infection acquired in laboratories were reported, during 1937 only one such case was reported. As was to be expected, most cases occurred among agricultural workers, yet in 1936 six physicians and eighteen veterinarians were also infected and in 1937 four physicians and nineteen veterinarians were infected.

#### Protection of the Youth Against Tuberculosis

A recent decree by the minister of the interior is designed to protect youthful domestic servants against infection from tuberculous members of a household. It is provided that a local health bureau as a routine duty must notify the head of a household which harbors a case of open tuberculosis that no young person can be employed in that house. If this order is violated with resultant harm to other persons, the householder is liable, both criminally and civilly, and may be placed in custody. Under certain circumstances the authorities can intervene. The health bureau can also serve notice on a householder enjoining him from employment of young persons in his domicile.

#### Prof G A Wagner Retires

Prof Georg August Wagner, for many years director of the women's clinic of Berlin University, the Charité, has been relieved of his post, having reached the age of retirement. He will, however, continue in his professorship on a pro tempore basis. A native of Prague, he is 65 years old. In 1917, after service as assistant at the Women's Hospital of Vienna, he became ordinarius in gynecology at the University of Prague, and in 1928 he was called to Berlin in a similar capacity. He has published a great deal on gynecologic problems, especially tuberculosis of the female genitalia and gonorrhea in females.

#### JAPAN

(From Our Regular Correspondent)

Nov 28, 1938

#### Dietetic Hospital Opened

The first dietetic hospital has been founded at the cost of 150,000 yen (\$40,000) attached to the Dietetic Research Institute, the director of which is Saeki, an authority on dietetics. The institute celebrated its inauguration November 8 in Tokyo. The hospital will be devoted to the treatment of diseases caused by deficiency of vitamins, and the betterment of constitutional predisposition, by means of dietetic treatment. In the calory room is a tank which looks something like a small submarine. Patients will be placed in this tank, which is isolated from outside, and their expired gases are to be carefully separated and measured. The hospital has only fifteen beds at present. The equipment is modern.

#### Memorial to Hideyo Noguchi

A memorial to the late Dr Hideyo Noguchi was completed in October. His admirers, hoping to preserve his place of birth, have rebuilt the cottage, which stands in a village in Fukushima Prefecture in northern Japan. Many people at home and abroad offered contributions, which will be used in part in planting trees in the garden about the house next spring after the snow has melted away. The trees will commemorate the contributors also. The opening ceremony will be held May 21.

#### Dr Hata Is Dead

Dr Sahachiro Hata, professor at the Keio Medical University and vice president of the Epidemic Research Institute, died of arterial sclerosis November 22 at the age of 66. He assisted in the research on arsphenamine when with Ehrlich in Germany in 1907. He was made a member of the Imperial Academy in 1933.

### Marriages

BENEDICT RAYMOND WALSKE, Independence, Wis., to Miss Mary June Leydorf, Toledo, Ohio, Nov 3, 1938.

JOHN G WISHARD, Wooster, Ohio, to Mrs Blanche K Pollock of Aspinwall, Pa., in November 1938.

WILLIAM EUGENE APPERSON, Charlottesville, Va., to Miss Ellen Cosby Carter of Halifax, Oct 29, 1938.

CLARENCE RHODES BENNETT to Miss Gay McKenzie, both of Eufaula, Ala., in Camilla, Ga., Nov 24 1938.

JOHN J MULLOWNEY, Nashville, Tenn., to Mrs Esther G Thomas of Wilson, N C., Nov 1, 1938.

ALEXANDER R ALTOSF, Los Angeles, to Miss Viola Louise Lichtenstein of Chicago, Sept 14, 1938.

ERNEST PERRY BLUNT JR to Miss Anna Heath Williams, both of Richmond, Va., Nov 5 1938.

ALLEN EUGENE HALCK, Atlanta, Ga., to Miss Irene Christie in Spartanburg, S C., Nov 20 1938.

HAROLD MCCOMB HOBART to DR IRMA HAZLETT BELK, both of Washington, D C., Dec 27, 1938.

WILLIAM W MEAD Guthrie, Okla., to Miss Eunice Ellen Sacia, Rockford, Ill., Sept 21, 1938.

## Deaths

**George Wilkins Swift** \* Seattle, Northwestern University Medical School, Chicago, 1907, member of the Western Surgical Association and the Pacific Coast Surgical Association, fellow and member of the board of governors of the American College of Surgeons, past president of the Pan-Pacific Surgical Association, Pacific Northwest Medical Association and the Pacific Coast Otolaryngological Society, a founder and past president of the Public Health League of Washington, served during the World War, president of the Neuro-Surgical Clinic, served in various capacities on the staffs of the King County Hospital Children's Orthopedic Hospital, Swedish Hospital and the Seattle General Hospital on the editorial board of the *Western Journal of Surgery, Obstetrics and Gynecology* and the *American Journal of Surgery*, contributor to the "Cyclopedia of Medicine", aged 56, died suddenly Dec. 18, 1938, in Whidby Island, Wash.

**Victor Hugo Bassett** \* Savannah, Ga., Johns Hopkins University School of Medicine Baltimore, 1903, instructor of pathology and bacteriology at the Northwestern University Medical School, Chicago 1904-1905, at one time professor of pathology at the Wisconsin College of Physicians and Surgeons and director of the Marks Laboratories of Pathology and Bacteriology, and associate professor of pathology at the Milwaukee Medical College, formerly assistant superintendent and resident pathologist to the Milwaukee County Hospital Wauwatosa, Wis., bacteriologist to the city health department 1908-1922, city health officer and county health commissioner, past president of the Georgia Medical Society, past president of the Southern Branch of the American Public Health Association, curator of the Georgia Historical Society, aged 67, died Nov. 3, 1938, of acute yellow atrophy of the liver following prostatectomy performed six weeks previously.

**William Miller Ford** \* New York University of Virginia Department of Medicine Charlottesville 1899, formerly clinical professor of obstetrics at the University and Bellevue Hospital Medical College, fellow of the American College of Surgeons, served during the World War at various times and in various capacities served on the staffs of the Manhattan Maternity Hospital Women's Hospital, St. Clare's Hospital, St. Vincent's Hospital and the New York Hospital for Ruptured and Crippled, aged 59, died, Nov. 26, 1938.

**Louis Israel Harris** \* New York Columbia University College of Physicians and Surgeons New York, 1905, chairman of the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association, 1927-1928, chief of division of industrial hygiene, New York City Department of Health, 1915-1917, director, bureau of preventable diseases, 1917-1926, and commissioner of health, New York City, 1926-1928, consultant in public health, aged 56, died, January 7, in the Mount Sinai Hospital.

**Hickson Field Hart**, Peekskill, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1886, member of the Medical Society of the State of New York, served during the World War, formerly member of the board of education, past president of the village and member of the board of trustees, at one time member of the state assembly, on the staff of the Peekskill Hospital, aged 75, died, Nov. 7, 1938, in the Doctors Hospital New York.

**Rand Percy Crandall** \* Medical Director, Captain U. S. Navy, retired, New York University of Pennsylvania Department of Medicine, Philadelphia, 1887, entered the navy in 1888 and retired in 1930 on or after attaining statutory retirement age, veteran of the Spanish-American and World wars, formerly member of the city board of health, aged 72, died, Dec. 8, 1938, in the U. S. Naval Hospital, Brooklyn, of pyelonephritis and bronchopneumonia.

**Samuel Leonidas Ledbetter Sr.**, Birmingham, Ala., University of Louisville (Ky.) Medical Department, 1879, member of the Medical Association of the State of Alabama, member of the House of Delegates of the American Medical Association in 1910, formerly on the staffs of St. Vincent's Hospital and the Hillman Hospital, aged 83, died, Nov. 30, 1938, of auricular fibrillation and fractured femur due to a fall.

**John Cicero Hutchinson**, Shady Valley, Tenn., University of Tennessee Medical Department Nashville 1907, past president of the Sullivan-Johnson Counties Medical Society, formerly postmaster and justice of the peace, member of the board of education, aged 67, died Nov. 12, 1938, in the George Ben Johnston Memorial Hospital, Abingdon, Va., of injuries received in an automobile accident.

**Lester Lovett Powell**, Portland, Maine, University of Pennsylvania Department of Medicine, Philadelphia, 1905, member of the Maine Medical Association, served during the World War, consulting physician to the Webber Hospital, Biddleford on the staff of the Maine Eye and Ear Infirmary formerly on the staff of the state hospital, aged 63, died, Sept. 30, 1938, of coronary thrombosis.

**Daniel George Castell** \* Pontiac, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899, past president and secretary of the Oakland County Medical Society, formerly city health officer, on the staff of the Pontiac General Hospital, aged 69, died, Nov. 16, 1938, in the University Hospital Ann Arbor, of carcinoma of the pancreas with metastases.

**Oliver Paxon Holt** \* Cincinnati, Miami Medical College Cincinnati, 1886, professor emeritus of medicine, University of Cincinnati College of Medicine, formerly professor of physiology and pathology at his alma mater, aged 77, on the staffs of the Cincinnati General Hospital and the Christ Hospital, where he died, Nov. 20, 1938, of uremia and malignancy of the prostate.

**J. Guy Hoover**, Boonville, Ind., Central College of Physicians and Surgeons, Indianapolis, 1904, member of the Indiana State Medical Association, member of the city council, for several years member of the school board, aged 59, on the courtesy staff of the Protestant Deaconess Hospital, Evansville, where he died, Nov. 7, 1938, of coronary thrombosis.

**Joshua Fanning Abel** \* Weynesville N. C. Baltimore University School of Medicine, 1892, member of the Southeastern Surgical Congress, fellow of the American College of Surgeons, for many years county superintendent of health, served during the World War, on the staff of the Harwood County Hospital, aged 70, died, Nov. 30, 1938.

**George Warren Hyde** \* Detroit, University of Michigan Medical School Ann Arbor, 1925, president of the Detroit Dermatological Society, served during the World War, on the staffs of the Eloise (Mich.) Hospital Shurly Hospital and the Harper Hospital, aged 40, died, Nov. 17, 1938, of coronary thrombosis and myocarditis.

**Benjamin Clyde Barnard**, Alliance Ohio Western Reserve University Medical Department, Cleveland, 1907, member of the Ohio State Medical Association, served during the World War, fellow of the American College of Surgeons, on the staff of the Alliance City Hospital, aged 61, died, Nov. 4, 1938, of carcinoma of the prostate.

**Lewis K. Onsgard** \* Houston Minn., Eclectic Medical Institute, Cincinnati, 1887, an Affiliate Fellow of the American Medical Association, formerly member of the board of health and coroner, company surgeon for Chicago, Milwaukee St. Paul and Pacific Railroad, aged 72, died Oct. 24, 1938, of cerebral hemorrhage.

**Martin Joseph Fardy** \* Minot, N. D. Washington University School of Medicine, St. Louis, 1918, fellow of the American College of Surgeons, served during the World War, on the staffs of St. Joseph's Hospital and the Trinity Hospital, aged 45, died, Oct. 27, 1938, in Los Angeles of cerebral hemorrhage.

**Hugh Elliott Eaglesham**, Weyburn Sask. Canada, Trinity Medical College Toronto, Ont. 1903, past president of the Council of the College of Physicians and Surgeons of Saskatchewan, at one time liberal member for Weyburn in the legislature of Saskatchewan, aged 66, died, Oct. 12, 1938.

**John Henry Wilms** \* Cincinnati, Pulte Medical College, Cincinnati, 1902, fellow of the American College of Surgeons, formerly professor of anatomy at his alma mater on the staff of the Bethesda Hospital, served during the World War, aged 59, died Nov. 26, 1938, of cirrhosis of the liver.

**Edward Thomas Dillon** \* Los Angeles, University of Southern California College of Medicine, Los Angeles, 1901, member of the Pacific Coast Surgical Association, fellow of the American College of Surgeons, formerly on the staff of St. Vincent's Hospital, aged 61, died, Oct. 14, 1938.

**Alfred Larson**, Savannah Ga., University of Illinois College of Medicine Chicago 1929, assistant city health officer and county health commissioner formerly associate in bacteriology, University of Georgia Medical Department, Augusta, aged 54, was found dead Nov. 3, 1938, of heart disease.

**Arthur V. Emerson**, Tulsa, Okla., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1902, past president of the Tulsa County Medical Society, formerly city superintendent of public health, aged 59, died, Oct. 29, 1938, in a local hospital.

**Philip Garfield Hood** ♂ Newark, N J, Columbia University College of Physicians and Surgeons, New York, 1904, served during the World War, on the staffs of the Newark City Hospital, St Michael's Hospital and St James Hospital, aged 57, died, Nov 19, 1938, in Port au Peck

**George Freeman Allison**, East Providence, R I, Boston University School of Medicine, 1891, for many years member of the school committee, formerly on the staff of the Homeopathic Hospital, Providence, aged 75, died, Nov 9, 1938 of coronary thrombosis

**George Waller O'Grady**, Rochester, N Y, Cleveland Homeopathic Medical College, 1899, director of the Monroe County Bacteriological Laboratory, formerly health officer of Lancaster, Ohio, aged 63, died, Oct 28, 1938, of carbon monoxide poisoning

**Chester Blaine Crumpacker**, South Bend Ind, Northwestern University Medical School, Chicago 1905, member of the Indiana State Medical Association formerly county coroner, aged 55, died, Nov 23, 1938, in St Joseph Hospital of cerebral hemorrhage

**Thomas Langford Butler**, Louisville, Ky, University of Louisville Medical Department, 1890 at one time professor of surgery and clinical surgery at his alma mater, aged 70, died, Nov 18, 1938, in a hospital at Baltimore of epithelioma of the right ear

**William Wesley Kergan**, Oakland, Calif, Michigan College of Medicine and Surgery, Detroit, 1892, aged 76, died, Oct 27, 1938, in the Stanford University Hospital, San Francisco, of lymphatic sarcoma and intestinal obstruction

**Hollis Lee Brownson**, Western, Neb, Jefferson Medical College of Philadelphia, 1920, member of the Nebraska State Medical Association, aged 51, died Oct 22, 1938, in a hospital at Lincoln of cholelithiasis, hepatitis and appendicitis

**Alexander Brumfield Taylor**, Des Moines, Iowa, Chicago College of Medicine and Surgery, 1909 aged 55, died, Oct 6, 1938, in the Veterans Administration Facility, Jefferson Barracks, Mo, of nephritis and secondary anemia

**Arthur E Becker** ♂ Brenham, Texas (licensed in Texas under the Act of 1907) past president and secretary of the Washington County Medical Society, aged 63, died, Nov 15, 1938 in St Francis Hospital of peptic ulcer

**John W Botts**, Glencoe, Ky, Louisville Medical College, 1897 at one time health officer of Owen County, aged 64 died in November 1938 in St Elizabeth's Hospital, Covington, of multiple abscesses and bacterial endocarditis

**George M Gowney** ♂ Rochester, N Y, University of Buffalo School of Medicine, 1906 on the staffs of the Highland Hospital and St Mary's Hospital aged 69, died, Oct 13, 1938, of duodenal ulcer and arteriosclerosis

**Emma L Sutro Merritt**, San Francisco University of California Medical Department, San Francisco 1881 Universite de Paris Faculte de medecine France, 1887, aged 81, died, Oct 17, 1938 of chronic myocarditis

**Henry L Curtis**, San Francisco, University of Pennsylvania Department of Medicine Philadelphia 1880 for many years member of the city board of health, aged 79, died in Oct 3, 1938 of cerebral hemorrhage

**Herbert Hall Plumer**, Union Maine Boston University School of Medicine 1898 member of the Maine Medical Association, on the staff of the Jones Sanitarium, aged 64 died, Oct 7, 1938, of hypostatic pneumonia

**David T Cardwell**, Gary, Ind Howard University College of Medicine Washington D C, 1905, formerly member of the board of health, aged 58 died Nov 18, 1938, in San Antonio Hospital of pulmonary tuberculosis

**Odia Martin Carter**, Monticello Ky, University of Nashville (Tenn) Medical Department 1905, Hospital College of Medicine Louisville Ky 1906, aged 59 died, Oct 28, 1938 of edema of the brain and lungs

**Shirley William Lane**, Kankakee Ill Chicago College of Medicine and Surgery 1908 member of the Illinois State Medical Society on the staff of St Mary's Hospital, aged 53 died, Nov 21, 1938 of myocarditis

**Raymond Francis Osborne**, Washington, D C Georgetown University School of Medicine, Washington 1920 aged 41, hanged himself, Oct 12 1938, at the Sheppard and Enoch Pratt Hospital Towson, Md

**William Stewart McMurray**, Multnomah Ore, University of Louisville (Ky) Medical Department 1908 member of the Oregon State Medical Society, served during the World War, aged 58 died Oct 9 1938

**Charles F Hitchcock**, Sodus, N Y, Homeopathic Medical College of Missouri, St Louis, 1891, member of the Medical Society of the State of New York, aged 76, died, Oct 22, 1938, of carcinoma of the prostate

**Reuel Earnest Bartlett** ♂ Berea, Ky, Vanderbilt University School of Medicine, Nashville, Tenn, 1907, aged 68, on the staff of the Berea College Hospital, where he died, Nov 4, 1938, of diabetes melitus

**Orlando Ducker**, Washington, D C, Jefferson Medical College of Philadelphia, 1877, veteran of the Spanish-American War, aged 88, died, Oct 22, 1938, of injuries received when struck by an automobile

**C Nelson Raymond** ♂ New Rochelle, N Y, Queens University Faculty of Medicine Kingston, Ont, Canada, 1891 on the staff of the New Rochelle Hospital, aged 73, died, Oct 6 1938, of heart disease

**Edward E Hummel**, Williamsville, N Y, University of Buffalo School of Medicine, 1897 at one time coroner of Genesee County, aged 64, died, Nov 17, 1938, in Bradenton, Fla, of cerebral hemorrhage

**George W Darling**, South Rye, Vt, University of Vermont College of Medicine, Burlington, 1882, member of the Vermont State Medical Society, health officer, aged 80, died, Oct 22, 1938

**James Clark Bell**, Bowmanville, Ont, Canada, M B, University of Aberdeen Faculty of Medicine, Scotland, and M D, in 1917, F R C S, Edinburgh, Scotland, 1920, aged 52, died, Oct 22, 1938

**John C Blossom**, Richmond, Ind, Kentucky School of Medicine Louisville, 1900, past president of the Wayne County Medical Society, aged 66, died, Nov 24, 1938, of carcinoma of the stomach

**Isaac Newton Sanders**, Salem, Ore, Willamette University Medical Department, Salem, 1900, member of the Oregon State Medical Society, aged 62, died, Oct 16, 1938, of coronary thrombosis

**T J Holton**, Groesbeck Texas (licensed in Texas, under the Act of 1907), member of the State Medical Association of Texas bank president, aged 68, died, Nov 1, 1938, of coronary thrombosis

**Olin Huntley Hoffman** ♂ Baltimore, Jefferson Medical College of Philadelphia, 1891 on the staff of the Franklin Square Hospital, aged 78, died, Oct 29, 1938, of coronary thrombosis

**Benjamin Clyne**, Yale Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883, aged 82 died, Nov 9, 1938, of carcinoma of the prostate and bronchopneumonia

**James Edward Trueman**, San Jose, Calif, McGill University Faculty of Medicine, Montreal, Que, Canada, 1881, aged 83, died, Oct 19, 1938, of carcinoma of the liver and secondary anemia

**Robert Walter Brown**, Santa Maria Calif, Manitoba Medical College, Winnipeg, Man Canada, 1893, aged 76, died, Oct 15, 1938, of cerebral hemorrhage and hypertension

**Daniel Philip Kincard**, Memphis, Tenn University of Tennessee College of Medicine Memphis, 1913, aged 48 died, Oct 2, 1938, of cerebral hemorrhage

**Edward Charles Krause**, Bridgeport Conn, Yale University School of Medicine, New Haven, 1902, aged 67, died Oct 8 1938 of coronary thrombosis

**Raymond Power Higgins**, Philadelphia Hahnemann Medical College and Hospital of Philadelphia, 1896, aged 63 died Oct 18 1938, of coronary thrombosis

**David Henry Williams Jr**, Chicago Rush Medical College, Chicago 1897, aged 69, died Oct 2, 1938

# CORRECTION

The location of the University of Pennsylvania Department of Medicine should obviously have been Philadelphia instead of Ann Arbor as mentioned in the obituary of Dr William Moore Guilford of Lebanon Pa, in THE JOURNAL January 7, page 74

## Bureau of Investigation

### "MAHATMA" WILLIAM ESTEP

#### A Disciple of Albert Abrams with a Long, Long Record

Prof William Estep once again appears on the medical horizon—this time the "professor" is promoting a device which he calls the "Estemeter"

#### ESTEP'S HISTORY

For years inquiries concerning William Estep, modestly urging himself as a 'Renowned World Traveler Educator, Philosopher, Exponent of the World's Religions, Founder of Super Mind Science, President of the Super Mind Science Temple,' and so on have come to the Bureau of Investigation. In one of his pamphlets, advocating a course of lessons in the mysteries of the Oriental sects and headed 'A Complete Sacrifice of Master Adopts Secrets to Make A Temple Possible in Detroit,' appears the following comic-on:

#### PROFESSIONAL MATTERS METHODS USED BY THE WORLD'S MASTER MATTERS

"Consisting of Metaphysical Methods to Stimulate and Control the body energy methods for Tuberculosis, Arthritis, Cancer and Ulcers, Blindness and many other so called incurable diseases. Hundreds of testimonials prove they are Master Methods. No Faith, No Suggestion, No Affirmations used. The methods are scientific and were formerly taught to physicians only. They are worth thousands of dollars (more or less) —I have arranged complete in a booklet for (Healers Only).

This work will be taught to 500 people only. After that it will not be taught. This is a sacrifice of a lifetime, practically given away at \$100.00 FOR THE FIVE DAY PERIOD.

#### YOU CAN BECOME

a Professional Analyst, Mind Reader, Healer, Occult Astrologer or Expert Psychologist. Platform Workers that are Experts can earn from One Hundred Dollars per week up to Thousands if they know their work.

ALL THAT IS NEEDED IS IN THIS COURSE OF LESSONS  
THIS IS THE WORK OF THE MAGI

Advertisements for a similar series of free lectures to be given in Chicago contain recommendations from officials of the local lodge of the Loyal Order of Moose in Pittsburgh from the "Executive Engineer" of the Satapur Canal, India, and from an "Indian King." A further inducement to those who 'fall for' this type of stuff is the following:

"If you want this course you must get it now as it will be soon taken off the market for good since it is only a temporary necessity that these great secrets gathered from all over the world will need to be sold. Two hundred is the limit—first come first served. Only need of immediate financial assistance would prompt Prof Estep to offer these wonderful secrets to his students.

What, Professor! You need financial assistance, but in ten days you can teach 'platform workers' how to make 'One Hundred Dollars a week up to Thousands'—"if they know their work." Did any one suggest that you subscribe to and attend your own course?

When Estep played Chicago in April 1930 he had the aid of a trained monkey and also a number of complimentary press notices. Estep claimed at that time that he had "degrees" from two universities—"Western University" of Portland, Ore, and the "College of Nutrition," Chicago. No "College of Nutrition" in Chicago, or "Western University" in Portland could be located.

About the only "degree" referred to in his advertising is detailed in what purports to be an abstract of an article accredited to the India Daily Leader, Lucknow, India, 1928, in which it is stated that Estep is "the only American to ever qualify to become a mahatma. He was sponsored by Swami Ram Karan Dass, India's most noted Master Prophet." The Indians also have a word for such promoters, but it is spelled differently.

A follower of Estep's admitted that the receipts from Estep's Chicago meetings were about \$40,000. Estep was charged with obtaining money under false pretenses and the case came up on June 18, 1930. Unfortunately, Estep was dismissed when he made restitution.

A report of the Chicago Better Business Bureau for July 1, 1930, containing an article headed "Estep in Trouble Again" reads:

Professor William Estep who was recently dismissed in a Chicago court is now accused of racketeering in his home town Detroit, Michigan. Warrants have been sworn out for Estep, his wife known as Dora L. Tillinger, Florence J. Sorell, Bascom W. Maxwell and Rev. Samuel Maxwell, charging the five with violation of the insurance law of Michigan 'with racketeering under the guise of religion and with obtaining money by false pretenses.

Estep's fraternity, the Order of Temple Builders has been obtaining memberships at \$10.00 including a supposed \$500.00 life insurance benefit to members under fifty. The Order and the Temple have no license to sell insurance and thus forms the basis for the technical charge.

In Chicago Maxwell presented himself as a voluntary convert and former minister. A Detroit resident advises the Bureau that Maxwell is Estep's brother in law and that most of the prominent workers are related either to Prof or to his wife. He also states that Estep's \$120,000 Super Mind Science Temple was paid for by zealous students but is in Estep's own name.

In Chicago Estep's business did not take on the aspect of a reform until after his arrest. In his lectures he used mystical demonstrations a live monkey and other well known stage devices to attract attention and funds. In court he became the most glib of men and even refused to let the State Attorney's fortune teller the proper atmosphere was lacking.

Detroit police raided the Temple at 51 Spruce Street and found only one man, a Kansas City insurance salesman according to newspaper account.

#### ESTEP'S LATEST PROMOTION

The Better Business Bureau of Kansas City, Mo. informed the Bureau of Investigation under date of March 24, 1933 that Prof William Estep was selling literature published by the Positive Christianity Publications, 1926 H Street N.W., Washington, D.C. and taking \$100 fees for courses leading to a degree he calls MSD (Doctor of Metaphysics). It was also stated that Estep had asked one person to invest \$1,000 in four of his machines which he calls 'Estemeters' and which are supposed to measure the energy of various glands. Later the Kansas City Bureau reported that the following item appeared under the heading "Corporations Chartered" in the Kansas City Daily Record (Aug 15, 1933):

Grand Estemeter Corp. Kansas City to manufacture buy sell and deal in medical supplies equipment machines and devices for therapeutic uses to manufacture buy and sell electrical appliances to build equip and maintain institutions for the treatment and cure of the sick to manufacture and sell Prof Estep's Grand Estemeter (patent applied for) to engage in the printing business to deal in health foods to deal in and dispose of such real and personal property and securities as are necessary to the conduct of said business. 50,000 shares par value \$1. \$50,000 authorized. William Estep Kansas City Kan. 25,500 shares. Dora L. Estep Kansas City Kan. 1,000 shares. Wallace Maxwell Kansas City Mo. 1,000 shares. The above named parties shall compose the board of directors. Walter R. Barnes atty. 710 14 Rialto Bldg., Kansas City, Mo. rep're entirety.

A physician has recently forwarded to the Bureau of Investigation an advertising folder for the Estemeter. This folder contains the by-line "Copyright 1933 by Prof Wm Estep." The material contained in it indicates such blatant ignorance that it is astounding that any one would ever bother putting it in type. Still harder to believe is the idea that it could induce the prospect to purchase one of these machines the reported cost of which is \$250 (price not mentioned in folder).

The device includes a single dial, a push button and a control lever and the informative 'U S Pat Pending. There are two leads for application to various parts of the body, and the dial reads from zero to 1000. According to this folder:

If Your Chords Are Normal They Register	
Pineal Gland 580	Controls mental processes head nerves
Pituitary gland 600	Controls bone marrow and size of the body also childbirth and delivery
Parathyroid gland 600	Controls healing of tissue
Thyroid gland 580	Controls nerves and digestion
Thymus gland 550	Controls energy change circulation
Spleen Gland 600	Controls disease resistance
Adrenal Glands 500	Controls heat and sex force activates the heart
Pancreas gland 550	Controls insulin production
Gonads 600	Controls sex function

What a burlesque on scientific endocrinology and on science itself!

Among other statements made in the folder are the following:

"Any dietitian who attempts to teach diet but cannot test your glands will fail. Because the vitamins in food feed the glands and we cannot supply vitamins which are deficient unless we know which vitamins are

needed to correct the gland function. Doctors who ignore the glands or use inefficient methods to examine them will fail to get their patients well because the gland deficiency is the only cause of disease.

Thus the professor clammers aboard current interest in the science of nutrition.

Prof William Estep is listed as inventor of the Estemeter, and, in a general discussion on the ductless glands and health, reference is made to the "wonderful" discovery of Dr Albert Abrams, once the apotheosis of quackery. Incidentally, "Mahatma" Estep wanders into the writings of two well known men of medicine. Reference is made to Dr Alexis Carrel's "Man the Unknown" and Dr G W Crile's (spelled Crille) "The Phenomena of Life." Among the statements concerning Carrel is the following:

He states he had witnessed demonstrations in Thought Transmission and had known cancer to be healed in two hours by the scientific application of Metaphysics which in its strictest sense means the raising of body vibration [not according to Webster—Ed]. This noted authority advises the medical profession to learn more about these electrical energies which are in the human body to perform a definite function.

It is stated under Crile's name that

This noted scholar offers his discoveries in this fascinating field to all interested in the subject.

Without stopping to catch his breath, the author of this pamphlet continues with these statements, which reach a new high in ignorance and pseudoscience.

The discoveries of all the greatest authorities in the field of Electronic Science seem to point to these fundamental facts of value in healing disease:

1 All disease is congestion of body electronic energy produced by a condition of low body vibration and temperature.

2 The low vibration of any organ including the ductless glands whose hormone produces balance of the forces of life can be measured in terms of body resistance by a special sensitive instrument.

3 Just as congestion is produced by low body temperature and low body vibration so can health be restored by raising the body temperature and raising the vibration.

4 As disease heels in the body so electronic energy increases at a corresponding rate and the increase can now be measured by special instruments. Thus the progress from disease to health can now be checked and understood in terms of increased electronic energy by a scientific knowledge of body electricity.

The "scientific" evidence back of the Estemeter is indicated in the following statement:

The inventor of the Gland Estemeter has experimented on thousands of patients in order to reach the norms of the different glands during this time he used the same method of correcting gland disorders which is now used by all technicians who use this invention [apparently all those who use it—use it—Ed] and the result was that in every case there were improvements while under the supervision of Dr J H Barkley of Indianapolis he demonstrated on Chronic Bronchitis, Palpitations, Tumors and various Arthritic cases the results were the same in all cases when the glands became normal on the Estemeter the patient was well if the patient was not well but improved the progress of the glands toward normal on the Estemeter was directly correspondent to the improvement noted in the patient. This physician who had practiced for forty years was astonished at the results. [He might have been at that if he had any way of knowing that the glands had not been and had become normal—Ed].

Of special interest in this folder is the following paragraph:

Who can use Estemeters? The Estemeter is now used in Kansas City by laymen. Since it does not diagnose disease or treat disease it is exempt under Medical license laws. The Health Food Salesmen make a chart of the glands for each customer then supplies the proper food shown on the Chart to correct Vitamin and mineral deficiency. The customer returns in about five days to check progress and get their second reading. When a Health Food Store uses an Estemeter they win thousands of new friends and always triple their sales. The Public Likes to Have a Correct Analysis.

It is stated in the leaflet that "The Gland Estemeter Registers the Power of the Glands—Reveals what vitamins are deficient, shows if the body is acid or alkaline, reveals the blood energy and its power analyzes the positive or negative, mental condition of the brain centers."

Disregarding the imaginative fantasy that is used in the promotion of this machine, the most astounding feature is the supreme audacity displayed by one who has never indulged in the study of science in promoting a machine to provide such information, since there is no such information. It was naturally expected, from the recent scientific developments in the fields of nutrition and endocrinology, that charlatans and

quacks would soon prostitute this knowledge. Whenever a new discovery is made in any field of science, the quack will exploit the discovery for personal gain. But who could ever have foretold that any one would concoct such a ridiculous device in an attempt to capitalize on the public interest in vitamins and glands?

The manner in which those responsible for this device have so blatantly bragged that it is exempt under medical license laws suggests a careful study of those laws to determine just how correct these boasts are. Even though those who use the device do not diagnose and treat disease by name, they claim to determine deficiencies and to treat those deficiencies by diet. The folder carries the following statements:

Notice—The Estemeter does not diagnose or cure disease. It reveals the cause so it can be eliminated.

Nevertheless, the intention is apparently that of diagnosis and treatment of conditions which should be under the purview of a physician.

Abrams promulgated his "Oscilloclast" to obtain the "vibratory frequency of disease." His device has had many successors. Although the application of the "theory" is different in the case of the Estemeter, the analogy is clear. This device is more vicious because it is suggested that a salesman use it on the credulous individuals who patronize "food fad" stores. Abrams has long since passed to his reward (?), but as a major prophet in the field of quackery he seems to have developed an inordinate number of disciples.

## Correspondence

### REACTION FROM MERCURY IN THE NEWBORN

To the Editor—Several months ago I was called to a small community hospital on consultation regarding repeated outbreaks of what was thought to be impetigo contagiosa. Despite constant routine treatment with 3 per cent ammoniated mercury ointment, strict asepsis and expensive sanitary repairing of two nurseries in succession, the eruptions continued to appear. Examination of three infants affected showed erythematous, papulovesicular eruptions in the axillary and crural folds, typical dermatitis due to mercury. There were also periodic attacks of diarrhea.

Since that time I have inquired at various hospitals about the occurrence of impetigo and diarrhea. While impetigo was found only sporadically, diarrhea among the newborn was fairly common and in some cases was so severe as to cause considerable concern.

At one large hospital there had been several cases of severe diarrhea thought to be infectious. Such cases continued to occur despite changing and repairing of the nurseries.

It was found that the rubber nipples and rectal thermometers were kept in a solution of 1:4,000 mercury bichloride. As the solution was kept for a considerable time, there is no question that its strength increased from evaporation. The infants were anointed for five days with 3 per cent ammoniated mercury ointment. When the use of all forms of mercury was stopped, the patients with diarrhea recovered from it and no new cases developed.

As a rough estimate, if they remained in the hospital for ten days and received ten feedings a day, their temperatures being taken once a day and if the equivalent of only one drop of mercury bichloride was on each nipple and thermometer, there would be ingested during this time 110 drops (0.001375 Gm) in a 1:4,000 solution, equivalent to 0.001016 Gm of mercury. In five days approximately 77.5 Gm of ointment would be applied to the skin, representing 2.325 Gm of ammoniated mercury, or 0.58138 Gm of mercury.

There is considerable disagreement as to the amount of absorption of mercury byunction. Such a study was made by Cole and his associates (*Mercurial Inunctions in the Treatment of Syphilis, *Arch Dermat & Syph* 27:1 [Jan] 1933*), a series of rubs with mild mercurous chloride were administered to six adult male patients, and even in this small series one patient showed salivation at the end of fourteen days, but this was dismissed as a probable idiosyncrasy. Possibly some newborn infants inherit an idiosyncrasy to mercury.

At the last meeting of the American Dermatological Society at Del Monte, Calif., several speakers mentioned the surprising increase in reactions from ammoniated mercury ointment, so marked that most dermatologists believed that only 3 per cent ammoniated mercury ointment should be used. This increase may be due to sensitization caused by the overvigorous prophylaxis of impetigo contagiosa. In the case reported here the prevention was worse than the disease. I believe that hospitals in which ammoniated mercury ointment is not used to prevent impetigo contagiosa immediately after delivery will show as few cases as those in which it is used.

J. G. DOWLING, M.D., Boston

### PREPARATIONS OF SULFANILAMIDE

*To the Editor*—We would like to correct a source of confusion regarding the terminology as used in our article "Peripheral Neuritis Following Sulfanil-Sulfanilamide (Disulfanilamide)" published in the Oct. 29, 1938 issue of *THE JOURNAL*, page 1641.

Disulon prepared by the Albra Pharmaceutical Company, Inc., is sulfanil-Sulfanilamide (synonyms DB 32, disulfanilamide, DPR 374, disceptal C).

Ulcron prepared by the Winthrop Chemical Company, is dimethyl disulfanilamide (synonyms, DB 90, DPR 373, disceptal A).

There is a third "disulfanilamide" compound termed Disceptal B, or DB 87, which is monomethyl disulfanilamide.

Patient 2 in the article received Ulcron, which was not furnished by the Winthrop Chemical Company but was obtained by the family physician from Germany. The other patients received Disulon.

R. S. WICKSON, M.D.

S. H. JOHNSON, M.D.

Philadelphia

### RECTAL ULCERATION FOLLOWING IRRADIATION

*To the Editor*—There is a discussion in the London letter on page 2316 of *THE JOURNAL* for Dec. 17, 1938, which appears to me not to take account of certain reports that have been published and the heading of which seems not to accord with the content.

The discussor deals with an article presented by Mr. T. F. Todd on page 1120 of the *Lancet* for Nov. 12, 1938. The article in the *Lancet* is properly entitled "Rectal Ulceration Following Irradiation" but the title of the article in *THE JOURNAL* is "Rectal Ulceration Due to Cancer of Cervix." The latter article seems to imply that the subject is new, stating "It is only recently that it has been discovered that the radium treatment of cancer of the cervix uteri may produce chronic ulceration of the rectum."

An article in which this condition was described was presented before the American Proctologic Society in June 1930 (*Factual Proctitis: A Justifiable Lesion Observed in Patients Following Irradiation, Internat Clin* 3:68-77 [Sept] 1930). Several articles have appeared since that time.

LOUIS A. BUIE, M.D., Rochester, Minn.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### TREATMENT OF PEMPHIGUS

*To the Editor*—I am treating a case of pemphigus vulgaris. The patient is a man over 70 years old and he has had this disease about four months. Have there been any new developments in the treatment of pemphigus?

M. D., Massachusetts

ANSWER—Sulfanilamide is the latest treatment for pemphigus (Caro M. R. Pemphigus Treatment with Sulfanilamide. Preliminary Report. *Arch Dermat & Syph* 37:196 [Feb] 1938). Caro used it in two cases. A man aged 52 with diabetes who had had a vesicular and bullous eruption for three weeks tested by the Pels-Macht photopharmacologic method, was given a rating of only 46 per cent, a confirmation of the diagnosis of pemphigus. Because of his diabetes the dose of sulfanilamide was kept low, 0.3 Gm (5 grains) four times a day. In a month of this mild treatment he made decided improvement. A woman aged 55, who had had pemphigus for a year and had been treated with various methods for nine months without benefit had grown decidedly worse and was apparently moribund. Given 0.65 Gm (10 grains) of sulfanilamide six times a day each dose followed by 1 Gm (15 grains) of sodium bicarbonate she developed a temperature of 102 F the second day and the dose of sulfanilamide was reduced to 0.65 Gm five times a day. On the fourth day the temperature became normal the skin showed improvement and the dose of the drug was reduced to 0.3 Gm five times a day. At the end of a week no new lesions had appeared.

Caro acknowledges that in each case a spontaneous remission of the disease might have been coincidental with the administration of sulfanilamide.

I am and I am (Treatment of a Pemphigoid Eruption with Sulfanilamide, *Arch Dermat & Syph* 37:840 [May] 1938) report a case of pemphigus in a farmer aged 48 who had had pemphigus for two months, with extensive eruption on the skin and beginning formation of vesicles in the mouth. Sulfanilamide was given 2.6 Gm (40 grains) a day, and in one week the eruption had subsided completely. The dose of the drug was then decreased to 1 Gm a day. An erythematous eruption appeared on the buttocks and posterior surface of the thighs on the sixth day, clearing up on reduction of the dose of sulfanilamide. A similar eruption was seen later on the face and hands. The medicine was discontinued and this eruption also vanished. At the time the report was made, the patient had been free of eruption for four weeks. The authors state that they realize that a much longer time must pass before a cure can be claimed.

Others have tried sulfanilamide for pemphigus without seeing any benefit from its use. It is probable that sulfanilamide will take its place with the Davis treatment, mercurochrome, quinine, trypanamide and many others which clear up certain cases of pemphigus often in spectacular fashion but fail dismally in others. The dangers of sulfanilamide therapy, particularly in those with pemphigus, whose resistance to toxins is already taxed heavily must be recognized and a sharp watch maintained on clinical signs, urinary disturbances and blood changes.

Older remedies are still achieving success in the treatment of pemphigus. A recent report by Brade (*Lebertherapie bei Pemphigus vulgaris, Dermat Wchenschr* 104:389 [March 27] 1937) reports success in two cases within a year by the administration of liver extract. At the time his report was written one patient had been well for six months, the other for nine months.

Loreti (Alcune considerazioni terapeutiche sul pemphigo vulgare, *Riv med* 53:1607, 1937) recently reported relief of a severe case of pemphigus by a series of six blood transfusions, one every second day.

It should be kept in mind that for every case cleared by any one of the many methods there are scores that resist every effort to control them. Pemphigus is subject to spontaneous remissions, unexplainable with our present ignorance of its etiology. That these are always coincidental with the administration of a new type of treatment seems doubtful, but they are often evoked as the explanation for its erratic response to treatment after a long effort has been unavailing. Riecke (*Handbuch*

*der Haut und Geschlechtskrankheiten*, Berlin, Julius Springer 7 527 [part 2] 1931) says "Pemphigus shows such a fitful and paradoxical spontaneous course that only too easily can erroneous conclusions on the value or lack of value of any line of treatment be drawn."

#### FOUR LEAD ELECTROCARDIOGRAPHY

*To the Editor*—I am somewhat confused with regard to the new method of taking the fourth lead with the electrocardiograph as described by Wilson. I have a Hindle electrocardiograph No. 017143 and I am taking the fourth lead with the left leg wire attached to the precordial electrode, the left arm wire attached to the left leg electrode and the right arm wire remaining attached to the right arm electrode. The lead switch is then turned to lead 3. I should like to know whether this method is the new method of Wilson and if so what the diagnostic criteria are in the fourth lead tracing taken in this manner in coronary infarction. I would appreciate it if you would give me this information or let me know where I can obtain it.

M D Pennsylvania

**ANSWER**—The connections described for obtaining the fourth lead are correct and probably the easiest way to obtain curves having the polarity advised by the special committee of the American Heart Association for the Standardization of Precordial Leads. A curve identical in all respects would be obtained if the left arm wire should be attached to the precordial electrode, the right arm wire connected to the left leg and the lead switch turned to lead 1, or if the left leg wire should be attached to the chest electrode, the right arm wire connected to the leg and the lead switch turned to lead 2. In all instances, in the recorded chest lead an upward deflection indicates positivity of the precordial electrode with respect to the leg.

Under these circumstances, infarction of the anterior heart wall causes in acute cases elevation of the S-T segment, which disappears usually within a few days and is replaced by sharply inverted T deflections. The QRS change seen in anterior infarction is the absence of the initial upward deflection or, in other words, the presence of Q waves. When infarction of the posterior myocardium occurs, depression of the S-T segment followed by the appearance of large upright T waves is seen. Characteristic QRS changes do not occur with infarction of the posterior heart wall. Wood, Wolfarth and Bellet have recently pointed out that marked depression of the S-T segment in the fourth lead may be a sign of infarction of the left lateral heart wall, as occurs after occlusion of the circumflex branch of the left coronary artery.

#### FALLING HAIR

*To the Editor*—I have noted your comment concerning dandruff in *THE JOURNAL* Sept. 10, 1938, page 1036 but no mention was made concerning loss of hair. I have had dandruff since the age of 15 and am now 45. Nothing from mange cure to sulfur and thirty other heroic measures has ever affected it. My hair has always been heavy until three months ago it is now getting thin—not an alopecia in one spot but generally thin as the result of falling hair. My health is excellent. I have no unusual worries aside from my inability to break 80. Can you suggest anything?

M D New Jersey

**ANSWER**—A rapid diffuse loss of scalp hair may be a toxic alopecia such as is seen several weeks after typhoid or influenza. Continued loss of hair for three months is a little too extended for this but not impossible. Looseness of the hair behind the ears is a strong argument for such a condition. If this is the case, the prognosis for the return of the hair is favorable.

If, on the contrary, the alopecia that has come on so rapidly is of the senile or seborrheic type, it will spare the low occipital hair and that on the sides of the head and behind the ears—and the prognosis is bad for anything more than arrest of the progress of the disease.

The treatment of the toxic and the seborrheic form is the same active stimulation of the scalp. Massage deserves first mention, performed at least three times a week by a professional masseur or daily by the patient. The lubricant used for this may well be a sulfur cream, from 5 to 20 per cent precipitated sulfur in rose water ointment. Other stimulants, such as 5 to 15 per cent oil of cade or rectified oil of birch tar, resorcinol monoacetate 5 per cent and salicylic acid 5 per cent may be also included.

Brushing the hair vigorously with a stiff bristle brush is an excellent form of massage. Other forms of stimulation are erythema doses of ultraviolet rays and painting the scalp with solutions of cresol in alcohol. Massage however, must be omitted during a sharp reaction to these methods. Both of them cause habituation, so that the dose of light or the percentage of cresol solution must be increased as the scalp becomes toughened.

After the acute loss of hair has been arrested, milder methods may be used. The favorite of dermatologists for many years has been an alcoholic solution of pilocarpine, 1 per cent or less

in 50 per cent alcohol or bay rum. This is said to have a specific stimulating effect on the growth of hair, possibly related to its action on the vegetative nervous mechanism.

Chloral hydrate, from 3 to 10 per cent in the same vehicle, or mercury bichloride 0.3 resorcinol monoacetate 6, spirit of formic acid 20, in bay rum or perfumed alcohol to make 120 may be used. If needed, 5 per cent castor oil may be added to the alcoholic lotions to prevent their drying tendency. Vigorous brushing however, should stimulate the production of enough natural oil.

The chief ingredient of all prescriptions for the control of alopecia is persistence. Furthermore, it is generally considered unwise for a physician to treat himself.

#### RED LINE OF GUMS NOT RELATED TO DENTURE

*To the Editor*—A man aged 65 had his teeth extracted two years ago. His gums healed normally and in the course of time a dental plate was prepared for him. He used the plate intermittently for one or two months but complained that he could not stand it because it hurt his gums in spite of the fact that the dentist insisted that it was a perfect fit. Ever since he wore the plate he has had a red line just outside the margin of the upper gums in other words on the labial side of the gums near the biting surface. This remains tender so that he cannot stand the pressure of a plate and cannot chew even semisolid food. The dentist is of the opinion that this is caused by sucking his gums which the patient denies. On the possibility that there might be a vitamin deficiency factor he has had a thorough course of vitamin medication particularly of vitamin C. I feel that syphilis and pellagra can be ruled out. He has been in the depressed phase of manic depressive psychosis for four years. Prior to that he was in the elevated phase. I have thought of the possibility of chemical irritation of the gums by the plate but since the plate has not been used for almost two years I do not see how this could be a factor at this time.

M D Virginia

**ANSWER**—It requires more than one or two months for a denture to be fairly comfortable after the extraction of teeth. The time required now is often reduced materially by surgical preparation of the mouth for dentures, which in such cases as this consists essentially of smoothing the outlines of the alveolar process. If this is left to be accomplished by nature through the absorption of the pointed spicules, it requires approximately two years. Many patients have said that for two years they could not bite with force on an artificial denture without having pain. Several cases have come to attention in a denture clinic in which a red line was noted, similar, it is presumed, to the one discussed in this case. These red lines were found in diabetic patients and in some patients with apparently a form of blood dyscrasia. In these instances the redness and tenderness have evidently not been caused by the denture because, as in the case cited, the line remained whether the denture was worn or not. It is apparently a symptom of the presence of a systemic condition. It is believed that the mental condition of the patient is not related and it is probably also not due to a vitamin deficiency. A careful physical examination to discover whether there is any systemic disturbance is advised and if not, that now, after the lapse of two years, new dentures be made.

#### COCOA AND CHOCOLATE

*To the Editor*—Please send me a list of contraindications to the use of cocoa. What is the active drug contained therein and what is its therapeutic action?

M D Utah

**ANSWER**—The chief active principle in cocoa and chocolate is theobromine (from 15 to 22 per cent) but it also contains small amounts of caffeine and tannic acid (0.16 per cent). Theobromine is similar in chemical structure to caffeine, found in coffee and tea, and its physiologic effects are also similar, though not identical. The principal effects are cardiac and respiratory stimulation, elevation of the basal metabolism, diuresis, and nervous and mental stimulation. A considerable tolerance may, however, be developed to these drugs so that the amount required to produce definite effects will vary with individuals. Theobromine differs from caffeine in the degree of effect produced though there are no precise experimental data on this point. Some authorities state that it is a more powerful diuretic but less of a nerve stimulant than caffeine. The amounts given clinically to produce physiologic effects range from 0.065 to 0.3 Gm (1 to 5 grains). Holt suggests 0.13 Gm (2 grains) at 5 years as a heart stimulant, and the U. S. Pharmacopoeia XI gives 0.2 Gm (3 grains) as an adult dose.

In considering cocoa as a beverage for children it should be regarded as a stimulant similar to coffee. If made with milk and a small amount of cocoa (two-thirds teaspoon per cup) the theobromine contained will be only about 0.03 Gm (one-half grain) if however, amounts up to from 1½ to 2 teaspoonfuls are used the theobromine content may be from 0.08 to 0.1 Gm (12 to 16 grains) or more. It would seem safe to conclude

from these facts that cocoa is contraindicated for young children at least and that if used at all for older children it should be in limited amounts, chiefly as a flavoring for milk. A fuller discussion of this question is given in the White House Conference Report, Growth and Development of the Child, volume III, pages 484-501.

#### NEPHRITIS IN ANESTHETISTS

To the Editor—I understand that some literature on nephritis in anesthetists has been published indicating that possibly there is an occupational hazard involved. If there is any literature with regard to this matter covering the disease and particularly its prognosis I would appreciate it if you will forward it to me. I have an anesthetist under my care who has nephritis at the present time and am anxious to obtain information.

M D Texas

ANSWER—There is not a great deal in the literature bearing directly on the question of nephritis among anesthetists when the nephritis is considered as being due to the effect of the inhalation of anesthetic agents. It is generally felt however that the amount of anesthetic agent inhaled by the average anesthetist is not sufficient to account for nephritis in an otherwise healthy person. Unusual circumstances might bring about such a condition, that is if an anesthetist is in the habit of inhaling either either deliberately or unintentionally because of the habit of keeping close to the ether. However in the literature regarding the effect of anesthetics on the kidney some workers have indicated certain results that may be expected if existing conditions are conducive to the development of nephritis in the patient. The following are some references to articles concerning this question:

Babacci and Behl. The Action of Ether and Chloroform on the Kidney. *Polidruco* May 1 1896. *Abstr. Brit. M. J. Epitome* 2 12 (July 12) 1896.

#### DERMATITIS FROM KUBOTON

To the Editor—Can you tell me anything about the contents of Kuboton, a German product used by farmers to kill bean beetles? It is a powder. I have a man with a severe dermatitis who has been using this substance. He is covered—body, extremities and neck—with a macular eruption like measles. The powder is sold by the Eastern States Cooperative Grange, Chilfonce, Ia. P. J. JUKENS, M.D. Ambler, Pa.

ANSWER—An insecticidal preparation, Kuboton, is used to kill bean beetles; it is manufactured by the Ansbacher-Siegle Corporation, Brooklyn. According to the label it contains cube resins 2.25 per cent, sulfur 4.75 per cent and inert ingredients 93 per cent. There have been cases of dermatitis reported from the Derris group, and it may be that the case in question represents another of these.

#### DERMATOSIS IN SUGAR WORKERS

To the Editor—Is there a furunculosis associated with working in sugar? Men who have been working in a beet sugar mill for twenty years state that there are sugar boils due to the juice's getting on their skin. These seem to be more prevalent than in men engaged in similar occupations and not exposed to the juice. What can be done for prophylaxis?

WILLIS P. BAKER, M.D. Santa Ana, Calif.

ANSWER—A variety of dermatoses have been described in work involving the handling of sugars, molasses and sugary fruits. So different are some of the lesions mentioned that specificity may be doubted. The lesion most frequently described is paronychia. The theory has been advanced that the sugar or syrup deposited at the base of the nails or otherwise on the skin serves as a suitable growth medium for common bacteria such as staphylococci and that "sugar dermatitis," "sugar onychitis" or "sugar boils" result. Other reports suggest that wetness, such as around sugar juices, either in the beet or in the

cane industry, is a contributory cause. In crude dried sugars, parasites have occasionally been encountered and on occasion they have been regarded as the source of skin disease among exposed workmen. Still further it may be observed that, in the class of workers in the beet and cane fields and at times in the sugar mills, personal hygiene possibly may be of a grade inferior to workers in general.

By way of prophylaxis best results are from strict attention to personal cutaneous hygiene. Among sugar mill grinders and in other operations that provide extensive wetness, such wetness and particularly drying on the skin of beet or cane juices should be avoided.

#### SUBACUTE BACTERIAL ENDOCARDITIS

To the Editor—Has any valuable therapeutic agent been found for subacute bacterial endocarditis?

M D New York

ANSWER—Subacute bacterial endocarditis, when unqualified, means *Streptococcus viridans* endocarditis. It is quite possible for other organisms to produce subacute bacterial endocarditis but it is a clinical fact that in about 95 per cent of the cases the bacterial cause is *Streptococcus viridans*.

There is no specific treatment for this infection. The mortality is still exceedingly high. Arsenic preparations still remain the favorite therapeutic measure. Sulfamylamide has been tried without appreciable effect.

Blood transfusion, used in addition to drug therapy, gives some encouragement. Transfusion from donors who have recently recovered from a streptococcal infection has been practiced. Donors have been selected and vaccinated with a stock *Streptococcus viridans* vaccine before the transfusion is given. A further step consists in making a vaccine from the organisms recovered from the blood of the patient. This vaccine is given to previously selected donors and transfusion is done when the donors have developed immune bodies.

In spite of these measures, the prognosis remains grave.

#### INHERITANCE OF MYOPIA

To the Editor—According to the fundamental laws of heredity if a man with a moderate myopia whose mother and two maternal aunts suffer from high myopia (no myopia on the father's side) marries a woman with moderate myopia none of whose parents, aunts or uncles have myopia would the offspring tend to be myopic and to what extent?

M D, New York

ANSWER—Refractive errors are so common in the human stock that their pattern in the mosaic of heredity is somewhat complicated. As a rule, myopia is inherited as a simple recessive character. This means that the man in the case in question inherits his myopia directly (RR). The mother and her two sisters are affected either because of a large number of siblings or else because of a union of two strains of myopia in her parents. The woman in the case with no known myopic relatives inherits through a mixed transmitter (DA), the myopia remaining latent in the transmitting parent. If all the siblings of her mother and father were known and were numerous, some would be found to be affected. The union of these two persons should result in a large proportion of myopic children. Theoretically all the children should have myopia, but it should be of moderate grade.

#### GALATEST FOR URINE SUGAR

To the Editor—Where can I procure material for the Galat test or Galatest for urinary sugar? An article appeared in the *Trained Nurse and Hospital Review* August 1938. Is it reliable?

O C AUSTUTZ, M.D. Bellefontaine, Ohio

ANSWER—Material for the Galatest for sugar in the urine can be obtained from the manufacturer, the Denver Chemical Manufacturing Company, 163 Varick Street, New York. The test is a modification of the Nylander reaction. It gives a rough idea as to whether the urine contains no sugar, a little sugar or considerable amounts of sugar. In the performance of the test a drop of urine is allowed to fall in the center of a small mound of the test powder. The presence of sugar is indicated by a brownish or blackish discoloration, the amount being roughly shown by the degree of darkening.

The test has the advantage of speed of performance and a minimum of apparatus. However, the test is not believed to be superior to Benedict's test, for the following reasons: 1 The powder is highly caustic and care must be taken to avoid damage to clothing, skin and mucous membranes. 2 It cannot be considered as accurate as Benedict's qualitative test. 3 Benedict's test is simple and requires little apparatus and time. Its use in this country is now so standard that patients and physicians everywhere are familiar with it. To introduce another test,

unless this is decidedly superior, seems unwise. It is only fair to add that in actual practice Benedict's test is not significantly influenced by uric acid, creatinine, cysteine or other substances and impurities as suggested in the article referred to by the inquirer. Rarely will the physician be led astray by a positive Benedict's test.

#### TREATMENT OF OLD X-RAY BURN

*To the Editor*—I am treating an x-ray burn of ten years standing suffered when a roentgen treatment was given for psoriasis. The burn is on the posterior surface of the right thigh. About every six weeks the glands in the right groin swell up and become tender, the entire leg swells up and becomes red and tender and the patient has chills and a temperature of from 102 to 105 F and is bedfast for several days. At these times hot packs are applied to take the swelling and pain out of the leg. Is there anything new in the way of treatment to offer? The patient is a man aged 34 a farmer the burn lvs him up about one sixth of his time.

A A THOMPSON MD Tyner Ind

**ANSWER**—The inquiry would imply that one may be dealing with an indolent ulcer, a thrombophlebitis or a lymphangitis or a combination of them. If the ulcer is extensive, excision followed by a transplant might be desirable. If a second degree dermatitis is present, swabbing the part twice daily with 2 per cent watery solution of gentian violet might help. The application of hot packs is good. There are no new satisfactory methods.

#### DAVIS SIGN IN ORTHOPEDICS

*To the Editor*—What is meant by the Davis sign in orthopedics? The only Davis sign I find in the dictionary relates to a condition of the arteries and is one of the signs of death.

E W MISKALL MD East Liverpool Ohio

**ANSWER**—There are so many so called signs described by almost every writer on any orthopedic subject that the "sign language" has become quite confusing, even to the orthopedic surgeons. The most recent sign described by a Dr Davis concerns an examination of the function and stability of the shoulder (Davis, Arthur G. A Conservative Treatment for Habitual Dislocations of the Shoulder, THE JOURNAL, Sept 26, 1936, p 1012). It supposedly demonstrates overdevelopment of the internal rotators and adductors of the shoulder following recurrent dislocations. It is probable that the sign referred to concerns the attendant change in position from anterolateral to posterolateral of the biceps and bicipital groove in patients who have had repeated dislocations of the shoulder.

#### IRON AND PULMONARY TUBERCULOSIS

*To the Editor*—Is the administration of iron contraindicated in secondary anemia when the patient has pulmonary tuberculosis?

MD Kentucky

**ANSWER**—It is not contraindicated so far as the pulmonary disease is concerned. Naturally heavy doses of iron by mouth will tend to aggravate an ulcerated gastrointestinal tract. In the presence of such a complication it may be better to give iron subcutaneously.

#### QUININE IN LATE PREGNANCY

*To the Editor*—I desire to comment about your answer to a question in the Oct 15 1938 issue of THE JOURNAL regarding antepartum administration of quinine. Since my paper in July 1936 reporting sixty personal cases treated ante partum with quinine I have collected more than 400 additional cases and the results were closely in line with the cases reported as to ease of labor and a decided lessening of time of labor. In my experience quinine is worthless as an oxytocic and is not used by me as such. The only fetal deaths that I have been able to find were caused by quinine used other than in small doses for several weeks preceding labor. All cases of deafness reported were also from larger doses and usually from an effort to induce labor or to strengthen pains both of which are foreign to the use to which I apply quinine. An idiosyncrasy in the mother is evidenced very promptly and the drug is as promptly discontinued which seems to obviate any danger to the fetus.

LINTON SMITH MD Atlanta Ga

#### HEMOPHILIA

*To the Editor*—I have just read on page 1953 of THE JOURNAL of Nov 19 1938 the question of Dr Burrows on hemophilia and the answer you gave to this question. May I take the liberty to correct your answer in that the first researches of Dr Bendien and myself on hemophilia (van Creveld S. *Maandschr v kindergeneesk* 3:351 [June] 1934; Bendien W M and van Creveld S. *Acta brev Neerland* 5:135 [1935]) pointed in the direction of a deficiency of a coagulation globulin in the blood of hemophilic patients. Our researches on the effect in hemophilic patients of human placental extract which pointed in the same direction were published later (Bendien W M and van Creveld S. *Acta brev Neerland* 7:No 6/7 1937 7:No 7 1938).

S VAN CREVELD MD Amsterdam Netherlands

Missouri October Examination

Dr Harry F Parker secretary State Board of Health of Missouri, reports the written examination held at Kansas City, Oct 18-20, 1938. The examination covered fifteen subjects. An average of 75 per cent was required to pass. Twelve candidates were examined, all of whom passed. The following schools were represented

School	Year	Per Cent
Howard University College of Medicine	(1937) 80.5	81.2
Rush Medical College	(1937) 85.8	86.2
School of Medicine of the Division of Biological Sciences	(1937)	79.9
Johns Hopkins University School of Medicine	(1938)	86.6
University of Michigan Medical School	(1933)	84.9
Meharry Medical College	(1937) 75.3	79.1
Universität Zürich Medizinische Fakultät	(1936)	83.9

Twenty eight physicians were licensed by reciprocity from October 3 through November 28. The following schools were represented

School	Year	Reciprocity
University of Arkansas School of Medicine	(1937)	Arkansas
Howard University College of Medicine	(1936)	Tennessee

Northwestern University Medical School	(1938)	Illinois
University of Illinois College of Medicine	(1932)	(1938) Illinois

University of Nebraska College of Medicine	(1936)	Nebraska
Ohio State University College of Medicine	(1931)	Ohio
Meharry Medical College	(1937, 5)	Tennessee

Book Notices

**Man and His Body** By Howard W. Haggard Director of the Laboratory of Applied Physiology Yale University New Haven Connecticut. With an introduction by Vandell Henderson. Cloth Price \$4.00. 394 pp. with 49 illustrations including 10 plates. New York & London Harper & Brothers 1938.

The introduction to this book was written by Prof Vandell Henderson. The book is intended especially for three classes of readers: employers and engineers in charge of labor, to whom it aims to give a practical understanding of what the human body is and college students, for whom it aims to afford a general acquaintance with medical science. The material has been used for years for undergraduate students in an elective course in Yale University in the form of lectures and a syllabus for student reading. The aim of the author is to give a general summary of the workings of the human body and to provide a discussion of the chief causes and processes of disease. The book is written in the usual fascinating style of the author. Among the subjects treated are chapters on the human machine and the source of its energy, digestion and its derangements, the lungs and their diseases, the nervous system its service and failures, reproduction and the organs of sex, and the principles of infection, immunity and allergy.

**Herman Boerhaave Commemorative Speech Delivered in the Aula of the Leyden University Hospital on Friday 23rd September 1938** By Dr D. Schoute. Paper 1p 20. Wassenaar Holland The Author 1938.

This is a speech delivered by the author at the Leyden University Hospital in Holland in September 1938 in commemoration of the two hundredth anniversary of the death of Herman Boerhaave. One can read this lecture and yet know little as to why Boerhaave was a great man although the reader will have been told many times that he was great. The author's English is at times awkward and repetitious. Boerhaave prepared for the ministry but in 1691, at the age of 22, turned to the study of medicine. He practiced in Leyden and came to be a professor of medicine, a professor of botany and still later a professor of chemistry. His breadth of knowledge brought him world fame. He was in poor health for many years before his death finding it necessary for associates to hold his classes. He was offered a position on the faculty of Groningen University in 1703 but declined. Boerhaave undertook clinical instruction at the bedside at St. George's Hospital in 1713, and although this type of instruction had been started in 1636 it acquired widespread popularity under Boerhaave's guidance. At the conclusion of the delivery of this address a statue was unveiled in memory of Boerhaave. There is a bibliography of thirty two references.

**The Adolescent** By Ada Hart Armit Ph.D. Professor and Head of the Department of Child Care and Training School of Household Administration and Graduate School of Arts and Sciences University of Cincinnati. Cloth Price \$2.00. 242 pp. New York & London Waltham House McGraw Hill Book Company Inc 1938.

This book was written for parents whose children are between 12 and 21 years of age. The author reviews the recent research on the period of adolescence that is especially valuable to parents in the guidance of their children. The social changes which are responsible for much of the adolescent's behavior are examined. These include the family pattern, which has changed from the patriarchal type of family to the democratic type prevalent today. The author considers that delayed marriage and the change in our educational systems also have caused many difficulties in the adjustment of adolescents. Earlier edu

cational systems were characterized by a minimum amount of reading, writing and arithmetic, with trade training under skilled workers for those who intended to enter the various trades. Until recently, general education for all children other than the three Rs, was not heard of. Now our elementary school system seems to be designed primarily to train children to enter college, with little attempt at training them for life other than to provide a large collection of facts, all of which they lose more or less rapidly. In some of the following chapters the author discusses discipline, training and emotional control growing up emotionally, character training education for home and family life, and planning the day for the older child. With regard to children of low or average intelligence and those with superior intelligence, when it comes to sound character and good citizenship the two appear to have an equal chance if their training has been in line with their capacities. High intelligence gives an adolescent an advantage over his fellows only if, by training and general equipment, he has also developed a sound personality.

**Beitrag zur Physiologie des Hirnstammes** Von Prof. Dr. med. Dr. phil. h. c. W. R. Hess, Direktor des Physiologischen Institutes der Universität Zürich. Teil 2. Das Zwischenhirn und die Regulation von Kreislauf und Atmung. Von Prof. Dr. med. Dr. phil. h. c. W. R. Hess. Paper. Price 26 marks. Pp. 127 with 114 illustrations. Leipzig: Georg Thieme, 1938.

In this monograph Hess presents the results of stimulation of the diencephalon in animals, chiefly cats. The technique employed was described in detail in a monograph published in 1932. In the place of faradic stimulation there was used a direct current interrupted about eight times a second and dampened by the presence of condensers and choke coils in the circuit. Hess believes that this type of current selectively stimulates autonomic paths and centers and makes it possible to activate these without influencing somatic functions. It may be doubted whether this is true in the central nervous system: the selection of the interrupted and dampened direct current as a means of stimulation was unfortunate. Many points in the thalamus, hypothalamus and adjacent structures were stimulated, the effects on blood pressure and respiration were recorded and the location of the stimulated points plotted on a series of photographs through horizontal sections of the cat's brain. The points which yielded rises in blood pressure and those which yielded falls were rather widely distributed through the diencephalon as were also points which yielded changes in the character, amplitude and rate of respiration. The results obtained in this investigation will be of interest chiefly to physiologists and cannot be summarized briefly. The typography is good and the illustrations are excellent. There is an index and a good bibliography.

**Surgical Pathology** By William Boyd M.D. LL.D. MRCP. Professor of Pathology, University of Toronto, Toronto. Fourth edition. Cloth. Price \$10. Pp. 886 with 491 illustrations including 15 colored plates. Philadelphia & London: W. B. Saunders Company, 1938.

This work is well known to every medical graduate. The importance of pathology to the surgeon can never be overestimated, nor will he always have a pathologist at his beck to diagnose for him. Dr. Boyd emphasizes this especially with regard to carcinoma of the breast, demanding ability on the part of the surgeon to make a gross diagnosis, agreeing in this wise with the precept of Lecene. However carcinoma of the breast is not always recognizable grossly nor does it ever call for an emergency operation such that the pathologist cannot be on hand. The continually changing concepts of pathology demand constant revisions in its textbooks even though certain fundamental tenets still remain. Dr. Boyd has in many ways admirably adapted this book to the newer pathology. The relation of endometrial phases to the ductless glands is suggested and a more rational use of endocrine therapy on the basis of the pathologic condition is indicated. Tumor grading, regional ileitis and the tumors of that confused group of ovarian lesions known as the granulosa cell type are new additions. Hypernephroma is properly indicated as a probable renal carcinoma. The method of grading tumors is discussed too briefly since the author utilizes grading as a partial basis for discussing certain carcinomas. The bibliography is recent and sufficient for further reference to almost any subject. The illustrations are clear

and in great number, including some excellent photomicrographs. One can best conclude with the words of W. J. Mayo: "It is a sincere attempt to place pathology before the student and the practitioner from the practical standpoint."

**The Child in Nursing** By Gladys Sellev, Ph.D. B.S. R.N. Instructor in the School of Nursing, Catholic University of America, Washington, D.C. Fourth edition. Cloth. Price \$2.50. Pp. 599 with 57 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

This comprehensive volume, dealing with the important problems of infant and child care from the nursing standpoint, seems to be excellent for students and a valuable work of reference for graduate nurses. The author has placed particular emphasis on the important points in the nursing care of the infant. Stressed also is the value of knowing the physiology and the anatomy of the well child as a comparative background. The book may aid in providing knowledge in the field of pediatric nursing not provided at present by the entirely too short school curriculum. The book covers the period from the first moment of extra-uterine life throughout infancy in both home and institution. Some of the methods of the treatment of asphyxia neonatorum are not those approved by various authorities. The wisdom of including so much material concerning treatment in a reference book for nurses is debatable. It is felt, however, that this knowledge imparted to the nurse may increase the value of her services to the patient and the physician. Questions and problems appended to each chapter aid in crystallizing in the mind of the reader important facts to be retained.

**A Short Practice of Surgery** By Hamilton Bailey, F.R.C.S. Surgeon, Royal Northern Hospital, London, and R. J. McNeill Love, M.S., F.R.C.S. Surgeon, Royal Northern and Metropolitan Hospitals, London. Fourth edition. Cloth. Price 28s. Pp. 996 with 818 illustrations of which 109 are coloured. London: H. K. Lewis & Co. Ltd., 1938.

This work, long recognized as a masterpiece in the field of surgical compends, underwent a painstaking and thorough revision enabling it to maintain the position of unusual popularity and superiority. Thanks to their erudition, the authors managed to include all that is new in surgery without increasing the number of pages, certainly an enviable and not easily attainable accomplishment. This has been done by omitting everything that is nonessential and by relegating rare conditions and polemic subjects to a smaller type. All important points are dealt with adequately, equal attention being paid to the pathology, etiology, clinical features and treatment of surgical conditions. The language of the text is terse and concise yet not dry; the illustrations are well executed. A perusal of all chapters revealed several minor omissions. For instance on page 67, among gas-forming bacilli, *B. aerogenes capsulatus* and *B. oedematis maligni* have not been mentioned. The post-operative treatment of thyroidectomy described on page 180 should include the use of morphine. In the description of hernia operations the Ferguson method, called the Girard operation in Europe, is not mentioned although it enjoys great popularity in many countries. The chapter on neurosurgery should include a brief description of ganglionectomy or ramisection for relief of pain caused by inoperable cancer of the uterus. Such minor omissions do not detract from the usefulness of this excellent book, which can be highly recommended not only to the students but also to general practitioners, who are given the opportunity to brush up on their knowledge of surgery in an easy and delightful manner.

**Doctor at Timberline** By Charles Fox Gardiner, M.D. Cloth. Price 43s. Pp. 315 with 25 illustrations by R. H. Hall. Caldwell, Idaho: The Caxton Printers Ltd., 1938.

The author was determined to practice medicine awhile in some wild place far from cities. He graduated at Bellevue Medical College, New York, interned at Charity Hospital, was a surgeon at the prison on Blackwell's Island and had a six-months surgical service in New York Hospital, but such places did not appeal to him. He started for the silver mining region of western Colorado in the heart of the Rocky Mountains with little money or experience, intending to try this sort of living for one year but he stayed fifty years. His has been the delight of seeing snow-covered mountains, breathing pure air, having

the sunshine and blue sky and of knowing men in the rough. At first he practiced in the silver camps, high, often above the timberline, with deep snow covering the ground for nine months in the year, then he moved to the cattle country at a lower altitude around 6,000 feet. Here he practiced medicine among cowboys, Indians, hunters, outlaws, gamblers and fugitives men rough in speech and action and yet with a fine regard for honor, honesty and truth. The author was 5 feet 7 inches tall and never weighed more than 110 pounds. He writes of narrow escapes from snow slides, of long horseback rides over dangerous mountain trails, of professional contact with lawless characters, of cutting and shooting affairs, of babies born in snow besieged cabins and of the companionship that a trusted horse and dog bring under such circumstances.

**Pharmacology Materia Medica and Therapeutics.** By Charles Solomon M.D. Associate Attending Physician and Chief of the Medical (Jewish) Hospital of Brooklyn. Collaborator Hazel Houston R.N. Instructor in Materia Medica School of Nursing Bellevue Hospital N.Y. Third edition. Cloth Price \$1.10 799 with 61 illustrations Philadelphia Montreal New York & London J. B. Lippincott Company 1938.

Because it is vitally important for the nurse to have an appreciation of the social problems resulting from the indiscriminate use of drugs an elaborate chapter on 'patent medicines' and self medication has been added. There has also been added a great deal of material at the end of each chapter consisting of a summary clinical correlation and ward practice topics for class discussion, notebook exercises projects for further study and review questions. As one looks over the closely printed material one wonders whether this book is not more suitable for reference than to serve as a textbook for nurses. Graduates in medicine would be well equipped if they knew what is contained in these pages. To require nurses to familiarize themselves thoroughly with the contents is almost inhuman. It is hoped that the teacher who uses the book in classes for nurses will make it clear what portions the nurse needs to memorize and what portions are chiefly included for reference purposes.

**Anus Rectum Sigmoid Colon Diagnosis and Treatment.** By Harry Elliott Bacon B.S. M.D. F.A.C.S. Assistant Professor of Proctology Temple University School of Medicine Philadelphia. Introduction by W. Wayne Babcock M.D. M.D. Professor of Surgery Temple University School of Medicine. Foreword by F. I. Lockhart Munnery M.A. M.B. B.C. Cloth Price \$8.50 Pp. 85, with 147 illustrations Philadelphia Montreal & London J. B. Lippincott Company 1938.

It is necessary only to study the bibliography appended to each chapter of this book to learn the amount of effort which the author has put into his work. He has collected materials from the works of many contemporary authors and has provided an exhaustive display of accepted opinions and procedures. The chapter on proctitis and sigmoiditis, although brief, provides a bibliography which includes 282 articles. The chapter on lymphopathia venereum is well done and almost every article of any importance which has ever been published on this interesting topic is listed at the end of the chapter. The volume is interesting, instructive and well illustrated and will prove of distinct value not only as an index to proctologic literature but also as a work of reference.

**The Special Pathological Anatomy and Pathogenesis of the Circulatory Respiratory Renal and Digestive Systems Including the Liver, Pancreas and Peritoneum.** By Horst Oertel Strathcona Professor of Pathology Director of the Pathological Institute McGill University Montreal Canada. Cloth Price \$8.50 Pp. 640 Montreal Renouf Publishing Company 1938.

This volume is an exceptionally good adjunct to textbooks of pathology for the physician who is interested in the physiologicopathologic processes underlying disease. The book is limited to the consideration of the pathogenesis of diseases of the circulatory, respiratory, renal and digestive systems. Under each system the author briefly reviews the structure and development of each organ with a nice selection of topics significant in pathologic processes. To this he frequently adds a summary of various experimental studies which throw light on the disease process to be discussed. From this point on the descriptions of the various diseases observed in each organ vary from short, concise statements of well established pathologic pictures and their relations to one another to a detailed historical account of the various theories of pathogenesis and the evidence support-

ing them. The purpose of the book, skilfully and logically maintained throughout, is admirably stated in the author's own words: "Any pathogenetic explanation which stops short of tracing the actual tissue changes in their causal connections fails to reach its purpose. We may be unable to accomplish this in many instances, but it is better to admit ignorance where we fail and not resort to pseudoscientific phrases or terms which simply cover ignorance instead of exposing it for further penetration."

**Ophthalmic Nursing.** By D. F. Grand. Foreword by A. C. Hudson M.D. M.A. M.B. Consultant Surgeon Royal London Ophthalmic Hospital London. Cloth Price \$1.75 Pp. 111 with illustrations Baltimore: William Wood & Company 1938.

This short handbook for ophthalmic nurses is divided into three parts: (1) a brief and simple description of the anatomy of the eye, a page devoted to explanation of refractive errors, and a short discourse on general principles of ophthalmic nursing; (2) an alphabetical list of some 100 terms and procedures commonly used with a simple explanatory note about each, and a list of fifty drugs commonly used with the method of use and strength of dilution; (3) a list of surgical procedures and the instruments employed for them. The book is short and all terms are defined with extreme simplicity. There are numerous good illustrations of ophthalmic instruments taken from the blocks of John Weiss and Son. The book might be useful for the instruction of student nurses in the pursuit of their general course but would hardly qualify for any advanced studies.

**A Textbook of Medical Bacteriology.** By David J. Belding M.D. Professor of Bacteriology and Experimental Pathology Boston University School of Medicine Boston Massachusetts and Alice T. Marston Ph.D. Assistant Professor of Bacteriology and Immunology Boston University School of Medicine Boston Massachusetts. In collaboration with the following members of the Department of Bacteriology Public Health and Preventive Medicine of Boston University School of Medicine Boston: Sanford B. Hooker M.D. Professor of Immunology Sidney C. Daley M.D. Dlp. Bact. Associate Professor of Bacteriology José P. Bill M.D. Dr. H. Assistant Professor of Public Health and Preventive Medicine and Matthew A. Derow M.D. Instructor in Bacteriology and Immunology. Cloth Price \$5.10 792 with 13 illustrations New York & London D. Appleton Century Company Incorporated 1938.

This textbook was intended to be intermediate between the voluminous reference books and the simple textbooks too elementary for medical students. The volume covers a mass of details in a sketchy manner. Only one aspect of controversial subjects is presented. In the field of bacteriology where knowledge is rapidly accumulating there are many disillusions awaiting the student who knows only one side of an issue. The illustrations in the book are excellent and the numerous tables which it contains are helpful in correlating information. This book should prove useful to the medical student in bacteriology.

**Text Book of Nutrition.** By J. A. Nixon CMG M.D. FRCP Consulting Physician to the Bristol Royal Infirmary Bristol and Doreen G. C. Nixon M.B. B.S. MRCS Recognized Teacher in Hygiene in the University of Bristol Bristol. Cloth Price \$6.00 Pp. 219 with 9 illustrations New York Toronto & London Oxford University Press 1938.

The authors have compiled a readable discussion of nutrition from the physiologic, clinical and dietetic points of view. The book is intended for the general reader, and detailed discussion of the chemistry of nutrition has been avoided. Numerous tables of food composition, which the authors point out "must not be regarded as possessing the reliability of Bradshaw's Railway Guide," enhance the usefulness of the book for those readers who wish practical information. The general intent of the authors to provide a brief, general discussion of "what the body does with its food" has been achieved.

**Needed Population Research.** By P. K. Whelpton Scripps Foundation for Research in Population Problems. Prepared under the auspices of the Population Association of America. Paper Price, \$1 Pp. 196 New York Milbank Memorial Fund 1938.

Interest in population research has increased greatly in the past few years. It is satisfying to note that this book reflects the true critical scientific spirit in that field, in fact the entire book is devoted to pointing out the faults in basic information and the means of bettering them, and to methodologic pitfalls which should be avoided. Numerous factors in this field of research are difficult to evaluate. Consequently there are many

problems which are faced in population investigations which are common to those of clinical research. As companionate sciences, population research and clinical investigation have much to learn from each other which should prove mutually beneficial.

**A Guide to Human Parasitology for Medical Practitioners** By D B Blacklock M D DPH DTM Professor of Tropical Hygiene Liverpool School of Tropical Medicine the University of Liverpool and T Southwell D Sc PhD A F C Sc Walter Myers Lecturer in Parasitology School of Tropical Medicine The University Liverpool Third edition Cloth Price \$4 Pp 259 with 124 illustrations including 2 colored plates Baltimore William Wood & Company 1938

This practitioners' handbook of human parasitology has proved its acceptability by attaining a third edition in three years. In the latest edition the chapter on malaria has been rearranged and that on leishmaniasis has been rewritten and the book as a whole brought down to date. Its usefulness would be considerably increased if the authors should include therapy and preventive measures in their next edition.

**Cancer Its Diagnosis and Treatment** By Max Cutler M D Associate in Surgery Northwestern University Medical School Chicago and Franz Buschke M D Assistant Roentgenologist Chicago Tumor Institute Chicago Assisted by Simeon T Cantrell M D Director Tumor Institute Swedish Hospital Seattle Cloth Price \$10 Pp 757 with 346 illustrations Philadelphia & London W B Saunders Company 1938

The opening chapter, entitled "Radiation Therapy," reflects the emphasis of this book on the treatment aspects of cancer. Brief discussions of biopsy and the spread of cancer follow. The book then considers the diagnosis and treatment of cancer in the principal anatomic locations. As stated in the preface, cancer of the central nervous system and questions of histogenesis and detailed morphology have been left to other works already available. The book is admirably illustrated. Although doubtless not all sections of the book will be equally accepted by other authorities in the field it may be considered an invaluable aid by all those who diagnose or treat cancer.

**Zur normalen und pathologischen Anatomie des Greisenalters** Von Prof Dr Ludwig Aschoff Sonderdruck aus Medizinische Klinik Paper Price 2.50 marks Pp 116 Berlin & Vienna Urban & Schwarzenberg 1938

This renowned pathologist has presented in a brief monograph the histopathologic changes in organs and tissues encountered in persons between the ages of 60 and 80 exclusive of the pathology of the specific cause of death, such as infections. In more than 400 necropsies on persons from 60 to 80 years of age the author found no case of death due to the aging process itself. There was always a specific disease, arteriosclerosis accounting for one fourth. The monograph is a valuable contribution to the pathologic physiology of aging.

**Doctors I Salute!** By Emilie Conklin Cloth Pp 93 with portrait Winona Lake Indiana Light and Life Press 1938

This is a collection of poems written by the author on numerous subjects related to the life and work of physicians. Some of these poems express beautiful thoughts, some are humorous and some are sad. Their style and meter varies some being in iambic pentameter iambic tetrameter trochaic trimeter and dactylic dimeter. Among the poems are 'A Call to Service,' 'Mountain Doctor,' 'Southland Trail,' 'To a Great Physician,' 'Accident Ward,' 'Court Case,' 'Standing By,' 'Country Doctor,' 'Martyrs of Medicine,' 'Gland Therapy and Lines to a Laboratory Sheep.' These poems constitute a tribute to physicians and their associates which will encourage, inspire and cheer them.

**A Synopsis of Physiology** By A Rendle Short B Sc M D FRCS Professor of Surgery University of Bristol Bristol and C L G Pratt M A M Sc M D Demonstrator in Physiology University of Oxford England Third edition Cloth Price \$3.50 Pp 325 with 25 illustrations Baltimore William Wood & Company 1938

This edition has resulted in the inclusion of more physiologic material than the book had included previously. The book has retained the form of a compendium and consequently there is room for criticism of dogmatic statements which need some qualification to be entirely correct. The statements made are however, digests of the currently accepted opinions and the book should be of great use to physicians who wish to brush up on their information for various qualifying examinations. As a guide for medical students it can be of little value.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Privileged Communications Right of Alleged Criminal to Bar Testimony of Physician Who Treated Victim**—The defendant shot a woman in the back and was convicted in the Queens County court, New York, of assault in the second degree. In support of a motion for a new trial, he contended the court erred in permitting a physician who had treated the victim to testify as to her condition. Section 352 of the Civil Practice Act of New York, he argued, that interdicts the disclosure by a physician of any information he acquires in attending a patient in a professional capacity and which is necessary to enable him to act in that capacity rendered the testimony of the physician inadmissible.

The question before the court was whether a defendant who has shot another person may avail himself of the protection of the privileged communications statute so as to seal the lips of a physician who treated the victim. The court thought that the application of the rule of privilege to the facts here involved was to be determined by the reasoning of the Court of Appeals of New York in *People v Harris*, 136 N Y 423 33 N E 65, as follows:

I should never be willing to assent to a construction or to believe in a legislative intent which would operate to convert a statutory provision protecting a patient from a damaging or objectionable disclosure into a protection for a person on trial for the murder of the patient.

Any other view, said the court in the present case, would permit a gangster, or any other criminal, to seal the lips of physicians who attend the criminal's victim, whenever sufficient pressure is brought on the victim to induce him or her to refuse to waive the privilege. For a court to place such a weapon in the hands of criminals was, the court said, unthinkable in the light of present day conditions. Furthermore, this view, in the opinion of the court was reinforced by the provisions of Section 1915 of the Penal Law of New York which provides, in part: "Every physician attending or treating a case of bullet wound shall report such case at once to the police authorities."

Thus, by express statutory enactment, a physician in New York is compelled to divulge privileged information to police authorities and such disclosure is for the purpose of investigation and prosecution. Hence, the court said, the foregoing section of the Penal Law acts as a waiver of the privilege ordinarily accorded information acquired by a physician in attending a patient.

The court concluded, therefore, that the testimony of the physician was admissible and the motion for a new trial was denied—*People v Lav* (N Y) 3 N Y S (2d) 251.

**Hospitals for Profit Duty of Hospital to Irrational Patient**—The plaintiff was admitted to the defendant hospital in a delirious condition and was placed in a ward on the second floor in which there was no other patient. The wife of the plaintiff, on being informed by a hospital nurse that the plaintiff was in no condition to be left by himself, remained by the patient's bed during the night. The wife, however, fell asleep and her husband got up from the bed and jumped or fell from a window to the ground. For the resulting injuries he sued the hospital but the trial court withdrew the case from the jury and entered a judgment of nonsuit. The plaintiff thereupon appealed to the court of appeals of Georgia division 2.

A private hospital said the court must exercise such reasonable care in looking after and protecting a patient as the patient's known condition may require. In the present case the hospital did not expressly designate the wife as her husband's caretaker for the night when he was injured, but, on being informed that his condition required the presence of some one throughout the night, she volunteered to undertake that supervision. So far as the hospital's duty to the patient was concerned the acceptance by it of the services undertaken by the wife cannot be said as a matter of law to have discharged that obligation. Furthermore the court said the duty of a hospital toward one for whom it undertakes to care cannot by agreement with a third person be reduced below that which the law generally

eracts. Whether or not the hospital, with the wife present in the ward where the husband was a patient, should in the exercise of ordinary care have reasonably apprehended that the patient, in his condition known to the hospital authorities, might have harmed himself, presented in the opinion of the court a question for determination of the jury.

The defendant hospital knew as shown by the chart which it kept and which was admitted in evidence, that the patient was 'mentally off' and that without adequate supervision he might escape from his bed and might harm himself. Should a reasonable consideration of these facts questioned the court, have caused the hospital in the exercise of ordinary care and diligence, to apprehend that the wife might not be able properly to protect him and that in his known condition, he might come to harm? The determination of this question the court thought was within the province of the jury and the trial court should have permitted the jury to make that determination.

For the failure of the trial court to permit the jury to pass on these questions, the court of appeals reversed the judgment of nonsuit.—*Fate v. McCall Hospital (Ga.) 196 S. E. 906*

**Workmen's Compensation Acts Death from Nephritis Following Herniotomy**—Where, said the supreme court of New Jersey, a workman sustains a hernia from an accidental injury arising out of and in the course of his employment necessitating a surgical operation and the shock of that operation 'lights up' a dormant nephritis from which the workman dies a finding that the death was in fact the result of the injury, and was an accident within the meaning of the workmen's compensation act is justified, even though it was not the natural result of the injury.—*Dunn v. Atlantic City (N. J.) 199 1 5*

**Physical Examinations Rights of Defendant When Plaintiff Offers His Injury as Evidence**—The plaintiff claimed that as he was driving his automobile he was struck by a piece of gravel thrown from the wheel of one of the defendant's busses going in the opposite direction. The piece of gravel, he alleged, shattered the left lens of his spectacles, driving four pieces of glass therefrom into his left eye. He claimed that he then drove six or seven miles to a physician, who removed the glass from the eye. He thereafter sued the defendant for damages. The trial court gave judgment for the plaintiff and the defendant appealed to the Supreme Court of Mississippi.

At the trial the plaintiff pointed to his eye in illustration of the testimony he was then giving. On motion of the defendant, the court ordered an examination of the eye by a specialist, who subsequently testified that there had been no traumatic injury to the eye, that an injury such as claimed by the plaintiff would invariably leave scars and that he had found no scars. The plaintiff's condition, in the opinion of this witness was due to congenital astigmatism not trauma. A general practitioner, testifying for the plaintiff contended on the other hand, that it would be possible for injury to have occurred to the eye by traumatism that would cause astigmatism and leave no scar. The trial court did not err, said the Supreme Court, in ordering the examination of the eye by the specialist. Where a plaintiff in a personal injury suit voluntarily exhibits the injured part of his body to the jury for inspection, that part becomes an exhibit in the case, like any other object or thing introduced in evidence, and the opposing party has the right to make such inspection of it as will enable him to explain, criticize or impeach its value as evidence and to that end have it examined by experts. The testimony of the general practitioner, in the opinion of the court, was no answer to the testimony of the specialist. Medical testimony that a certain thing is possible is no substantial testimony at all. Unless such testimony is in terms of probabilities, it is not probative.

The question considered by the court to be vital in the case was whether or not a person with four pieces of shattered glass in his eye, large enough to be taken therefrom and preserved and exhibited in a trial, could have driven an automobile some six or seven miles, immediately following the alleged injury, with the pieces of glass still embedded in the eye. Conceding that it was possible, the court pointed out that evidence which is inherently unbelievable or incredible is not sufficient to sustain a verdict. There is no part of the human anatomy,

said the court, more sensitive to injury than the eye, or where the pain and distress resulting therefrom is more distracting. The eye involuntarily closes even to a gust of dust or sand, and an injury to one eye sets up an involuntary sympathetic response from the other. So the court, it was clearly improbable for the plaintiff to have driven as he testified he did. While, if the court said, the evidence was sufficient to prove that the plaintiff was struck in the eye, it was insufficient to prove that he suffered any such injury as claimed by him. The court accordingly affirmed the judgment as to liability but reversed and remanded it as to the amount of damages.—*Feche Lines, Inc. v. Bount (Miss.) 179 So. 747*

**Malpractice Metal Probe Left in Patient**—The plaintiff aged 11 years, was taken ill with influenza, Feb. 16, 1931. Double pneumonia followed resulting in empyema. About the middle of March 1932 the attending physician made an incision in the patient's left side and inserted a tube for drainage. In treating the patient, the incision was probed from time to time with a metal probe to determine whether there was any pus in the pleural cavity. The process of probing was begun in the summer of 1932 and continued until the early spring of 1933. The attending physician died, Nov. 13, 1933 just after dismissing the plaintiff as well. In August 1934 there was a recurrence of the empyemic condition. In February 1935 another physician performed an operation on the patient and removed two pieces of metal from the patient's side, which it was contended was the probe used by the attending physician in 1932 or 1933. Thereafter the patient by her guardian sued the administratrix of the estate of the deceased attending physician alleging that the physician negligently permitted the metal probe to drop into the patient's pleural cavity. Judgment was given for the plaintiff, and the administratrix appealed to the Supreme Court of North Carolina.

Conceding that the evidence was sufficient to carry the case to the jury the Supreme Court was of the opinion that a new trial must be awarded for error on the part of the trial court in permitting the plaintiff to recover hospital and medical expenses from the time she was taken ill in February 1932. The process of probing the court pointed out, did not begin until the summer of 1932, and it continued through the early spring of 1933. The plaintiff was not entitled to recover for hospital and medical expenses incurred prior to the alleged negligence of which she complained. While the trial court in one instruction said that the plaintiff was entitled to recover for medical and hospital bills 'to the extent that they may or have been incurred as the proximate result of the injuries complained of,' the court immediately added 'She contends they are about fifteen hundred dollars.' This contention was based on the evidence of the plaintiff's mother that the total cost of her illness from and after February 1932 was about \$1,500. Moreover, the Supreme Court continued the two metal pieces were removed from the plaintiff's side in February 1935 and there was no evidence that the recurrence or continuance of her empyemic condition was affected by these pieces after their removal. The trial court instructed the jury, however, to consider the plaintiff's suffering and the condition that prevailed from and after February 1932 through July 4, 1936.

For these errors committed by the trial court, the Supreme Court ordered that a new trial be awarded the defendant.—*Blaine v. Lyle (N. C.) 196 S. E. 833*

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Outbreak of Type I Pneumococcus Infection**—Gilman and Anderson present evidence that pneumococcal infection may be manifested by pneumonia, by suppurative otitis, by earache and at times by a 'cold' or sore throat. Such an outbreak occurred in February and March 1935 in the adjoining villages of Griswoldville and Shattuckville, Mass. A high incidence of suppurative otitis was associated with this outbreak. There was a much higher incidence of cases in the lower age groups, both in infected families and in the general population. Cultures taken from a cross section of the general population showed that 1 Unless a specific search is made for the pneumococcus, the true etiologic agent might be missed. 2 There was a higher incidence of type I pneumococcus in family contacts of cases than in the general population without such contact. 3 Healthy carriers were confined to the adult age group. 4 Although most of the positive throat cultures had become negative within two weeks after the first positive culture, some might remain positive for three months or more. 5 The prevalence of pneumococci other than type I was about the same in families with probable pneumococcal disease and in families without such disease. The authors suggest that the probable focus of spread was a mill, from which patients and adult healthy carriers spread the organism to the individual homes.

**Control of Sylvatic Plague Vectors**—Stewart and Mackie state that the control of fleas in rodent burrows, as well as control of the rodents themselves, necessary in the effective suppression of sylvatic plague may be accomplished by fumigation with methyl bromide. All stages from the egg to the adult are susceptible to this fumigant, but the adults are more easily killed than are the immature stages. It appears from field tests that the dosage of liquid methyl bromide, approximately 10 cc per burrow opening ordinarily used to kill ground squirrels is also sufficient to kill the fleas in all stages of development. In fumigating warehouses and the like the air and gas should be kept in circulation by means of fans in order to prevent stratification of the gaseous methyl bromide. Thus not only increases the efficiency of the fumigant but also reduces human hazard. Thorough ventilation should be provided on the completion of fumigation of cars, ships, rooms or buildings. It is believed that the spread of bubonic plague occurring through the transportation of plague-flea infested grains, cereals and the like may be effectively checked by fumigating these cargoes with methyl bromide and that the materials so treated will not in any way be rendered unfit for human consumption.

**Coronary Thrombosis Among Women**—Baker and Willis report the study of 100 cases of coronary thrombosis in women. Previous data disclosed that there was a marked predominance among men, the ratio of men to women was seven to one. It was also shown that coronary thrombosis occurred considerably later (six years) in life among women than it did among men. Only eight of the 100 patients were less than 50 years of age at the time the thrombosis occurred. The average age for the group was 63, clearly demonstrating the tendency for coronary thrombosis to occur later in life among women than among men. Fifty-four patients were dead at the conclusion of this study and in all but nine of these women death was directly attributable to the heart. In thirty-two patients death occurred soon after coronary occlusion and in thirteen later, as a result of ensuing congestive cardiac failure. In four women the cause of death could not be determined in five death resulted from diseases entirely unrelated to the heart. Seven patients suffered from recurrent coronary thrombosis. This incidence is considerably less than that noted in the previous study, which comprised both men and women. In that study the incidence of recurrent episodes was found to be 19 per cent. In seventy-eight women subjective evidence of cardiac disease occurred before the onset of coronary thrombosis. Sixty-six patients were known to have had hypertension before the onset of coronary thrombosis. Data regarding diabetes mellitus were available in twelve women. Sixteen patients had proved disease of the gallbladder. Nine patients lived less than twenty-four hours following the onset of the occlusive episode. Six patients lived less than a week, eight less than a month and nine less than six months. Six patients lived less than a year, four lived less than two years and only three lived more than two years. The average duration of life in the patients who died of cardiac disease was eleven months. Of patients in whom coronary thrombosis did not prove fatal twenty-eight were alive within a period of five years following coronary thrombosis, twelve were alive within a period of from five to ten years and three lived more than ten years. Three patients could not be traced. Eighteen patients reported their state of health as good, five said that they were well with the exception of occasional anginal seizures, fourteen were only in fair health and six were in poor health. The latter include patients who had severe recurrent anginal seizures, severe dyspnea, congestive cardiac failure or a cerebral vascular accident.

**Oral Typhoid Vaccination**—Crimm and Short vaccinated 100 patients subcutaneously with mixed typhoid vaccine and 100 by the oral method. Blood serum agglutinins were determined at various intervals. Of the patients who received the oral typhoid mixed vaccine 33 per cent had mild reactions, none of which were incapacitating. Significant agglutinin titers with oral typhoid vaccine were present within sixty hours. The agglutinin titration of both methods was essentially comparable after an interval of from two to five weeks. Significant titers persisted for six months or longer following oral vaccine. Those

cases failing to show agglutination five weeks following vaccination were 24 per cent for the subcutaneous and 8 per cent for the oral cases. Thus the failures are three times as numerous with the subcutaneous as with the oral method. The authors conclude, from the extensive clinical reports of others and the present laboratory results, that the oral method is as efficacious as the subcutaneous method of mixed typhoid vaccination.

**Cigaret Smoking**—From a study of six patients whose main symptom was a fatigue that was relieved by discontinuing smoking, Segal found that cigarette smoking can be the cause of fatigue in some people and this fatigue can be relieved by stopping cigarette smoking. Cigaret smoking produces definite changes in the electrocardiogram, mainly an increase in the cardiac rate and a lowering of the T wave. Standard and so called demounted brands of cigarettes produce the same effects. Although filter holders decrease the amount of nicotine in cigarette smoke, a sufficient amount of nicotine is still available to produce changes in electrocardiograms. These effects occur mainly in persons less than 50 years of age.

**Metabolism of Estrogens in Women**—The metabolism of estrogenic hormones by women first engaged the Smiths' attention when they observed that the oral administration of estrogen resulted in increased urinary excretion only during the luteal phase of the cycle. They quantitated theelin and theelol in (1) four specimens of urine from a normally menstruating woman at crucial times in the cycle, (2) ten urines from a patient with dysfunctional menstruation and (3) eighty-eight urines from seven normal, nine toxicemic and two eclamptic late pregnancies. Clinically the determinations indicate that 1 Endometrial bleeding is associated with both increased production and increased destruction of estrogen, which processes accompany a state of progestin deficiency, and this situation is exaggerated in dysfunctional menstruation. 2 The manifestations of preeclampsia coincide with changes in the urinary values for pregnandiol theelol, theelin and estradiol which reflect a progestin-deficient metabolism of the estrogens. It is postulated that the vascular phenomena which are responsible for endometrial flow and preeclampsia may be brought about by a toxic concentration of nonestrogenic breakdown products, resulting from destruction of the estrogens. The treatment of preeclampsia with progesterone and estrogens appears to shift the progestin-estrogen balance in the direction of normal and offers some promise of value, provided injections are started sufficiently early.

**Nonirritating Medium for Uterosalingography**—Titus and his associates find that monoiodomethane sulfonate of sodium (skiodan) (40 per cent) with acacia (20 per cent) is nonirritating in uterosalingography. It does not release free iodine and is rapidly excreted from the body through the urine. The acacia, added for viscosity, does not have a foreign body effect as do poppy seed or sesame oils. The authors have used

the compound in their clinic in a series of patients over a period of nearly two years without clinical evidence of inflammatory or other reactions, either immediate or delayed. Moreover, the roentgenograms appear to be more distinct than with the iodized oil preparations. It is suggested that this preparation may be of distinct use in bronchoscopic work.

Treatment of Undulant Fever W. Tilton New Haven—p. 616

**Syphilis and Marriage**—Shea states that every person with syphilis should be considered individually in determining fitness for marriage. Consideration must be given to the duration of the disease and the sex of the infected person. Women are less eligible than men, as primary, secondary and tertiary syphilis is communicable to the offspring. If women do marry, it must be with the assurance that they will take treatment throughout pregnancy regardless of the blood reaction. Also of importance is the amount of treatment received by the infected person at least eighteen months in early syphilis. Of course additional treatment is required for cure. The final consideration should be given to the economic responsibilities of the marrying persons as well as to the social rights of the community. Young and recently infected partners with a prospect of children and an insecure economic future would certainly be less eligible than elderly, noninfectious individuals who are economically comfortable and beyond the child bearing period. There are cases, of course in which because of legal entanglements (illegitimacy and the legalization of common law marriages) the physician may conscientiously disregard any of the usual standards and certify a person for marriage. At no time should the inconvenience of a postponed marriage interfere with the certifying physician's judgment, and just as exacting should be the duty of the judge of probate who has the power to waive the blood test law.

**Bactericidal Effect of Sulfanilamide on Streptococci**—White and Parker studied the bactericidal action of sulfanilamide on beta-hemolytic streptococci *in vitro* at an elevated test temperature. The fact that bactericidal action had been observed with the drug in whole blood at 40 C., when

only inhibition could be demonstrated at 37 C, led them to conclude that the temperature at which bacteria were subjected to the action of the drug determined whether sterilization or inhibition would result. It is difficult to draw definite conclusions from results with a test mixture which contains not only the drug and bacteria but leukocytes and serum as well. In plain PD broth, on the other hand, it seems to them that there can be no question of bactericidal action on the part of any element other than the drug itself. With such a mixture one is obviously dealing only with bacteria multiplying in an environment which includes nutritive elements, metabolites and drug. Under these conditions it appears that temperature is the determining factor. Although the authors have repeatedly verified their bactericidal results at 40 C, they have thus far been unable to obtain data which will explain just why the streptococci are killed by the drug at 40 C when they are merely inhibited at 37 C under conditions otherwise similar. The significance of a bactericidal action with sulfanilamide at 40 C *in vitro* should not be overlooked. Bactericidal action with this drug has been demonstrated by them only at elevated temperatures corresponding to those associated with high fevers. This suggests a correlation with successful clinical treatment of patients with severe hemolytic streptococcus infections involving high temperatures. Hence in rapidly successful sulfanilamide therapeutics it may be that the invading bacteria have been exposed at times to the action of the drug at temperatures similar to those at which bactericidal action has been demonstrated *in vitro*.

**Pulmonary Ventilation in Artificial Respiration**—King compared the pulmonary ventilation of twenty-one conscious male subjects during application of the Schafer, the Holger Nielsen and Drinker's "combined" methods of artificial respiration. The Drinker combined method gave the greatest respiratory exchange per respiration. It was administered at the rate of five a minute, it caused no discomfort when applied to a conscious subject. It is concluded that this method has definite value as an alternative method to the Schafer prone pressure technic. It has the advantage, as far as the subject is concerned, of adequate ventilation when applied at a slower rate. By increasing the rate a greatly augmented ventilation could be effected. When used with the inhalator this method would be of value in cases of carbon monoxide poisoning.

**Treatment of Neurogenic Megacolon with Drugs**—Klingman believes that, clinically, idiopathic or acquired megacolon falls into one of two groups: rectosigmoidal achalasia, in which one finds a failure of the rectosigmoidal apparatus to relax, and the group in which the motor function of the parasympathetic system fails to act effectively above the rectosigmoidal region. Rectosigmoidal achalasia may arise from two causes: overactivity of the sympathetic system resulting in spasm of the rectosigmoidal apparatus and failure of the parasympathetic system to inhibit properly the rectosigmoidal apparatus. Drugs acting exclusively on the parasympathetics as paralyzers are beneficial in establishing better emptying of the intestine in certain cases of megacolon. The drug of choice to inhibit liberation of acetylcholine should be atropine, but its highly toxic effects contraindicate its administration. Therefore for a less toxic atropine-like compound, syntropan (the ester of 3-dimethylamino 2,2-dimethyl-1-propanol and tropic acid) was selected. It was selected because it controls tonus without interfering with the peristaltic reflex. Clinically the two types of rectosigmoidal achalasia cannot be distinguished except after trial of appropriate drug therapy, but through the use of barium sulfate enemas it is frequently possible to demonstrate whether or not there is rectosigmoidal spasm with or without delayed emptying of the colon. In cases of rectosigmoidal achalasia there is marked delay in emptying, whereas in the cases in which there is deficient motor function on the part of the parasympathetics of the colon above the rectosigmoidal apparatus there is good emptying of the lower colon but retention of the barium sulfate in the upper part of the colon. Based on this classification, the author proposes a selective form of treatment for each of the conditions classified. When an x-ray interpretation makes it possible to establish that the rectosigmoidal apparatus is functioning, prostigmine methyl sulfate should be tried. If the rectosigmoidal apparatus is not functioning, amphetamine sulfate and then syntropan should be tried. If there is no response to either of the latter drugs, lumbar ganglionectomy and presacral resection is proposed until a more satisfactory selective drug can be found.

### Treatment of Hypogonadism in the Adolescent Male

—Webster used replacement therapy in six adolescent males with true hypogonadism as soon as the condition could be definitely detected. Of the six boys, two were typical of the so-called Frohlich's syndrome, one was considered an instance of primary hypogonadism without a history of previous disease or trauma of the testes and without evidence of other endocrine disorder, two were bilateral cryptorchids both of whom had had previous operative procedures, and one was an example of a severe constitutional disease causing retardation of sexual development. Treatment with testosterone propionate brought about increased genital growth and the secondary sexual characteristics usually associated with normal puberty. Whether treatment must be continued for the remainder of the individual patient's life is not known. Although regression of genital growth probably will not take place after the cessation of treatment it is to be expected that small maintenance doses must be given in order to maintain libido, hair growth and the various other functions apparently dependent on a normal level of androgenic hormones in the blood. About 25 mg of testosterone propionate three times a week seemed to be an adequate dosage. In no instance was excessive libido apparent. Smaller doses of 10 mg two or three times a week appear to be adequate to maintain beard growth, libido and the like after they have been established. A careful study of more cases is necessary.

in order to obtain additional data on the subject of clinical dosage. The first change, following the injection of testosterone propionate, was the appearance of pubic and axillary hair. An increase in the size of the penis, development of the scrotum and deepening of the voice soon followed. Growth of beard and an increase in the size of the prostate occurred only after several weeks of treatment. Three patients gained weight. However, these patients looked less obese at the end of the period of treatment than at the beginning. There was a decrease in the size of the mammary region and the abdomen. Growth spurts were noted in every boy during the period of treatment.

**Obesity.**—Hancock states that the obese person, child or adult, is often potentially diabetic. Various orthopedic conditions, ranging from pronated feet to Pott's disease, are associated with overweight which in some instances causes, in others aggravates and in all renders treatment more difficult. Obesity increases the risk in surgical conditions, pneumonia and other medical crises. Obese children are often objects of ridicule by their playmates. This sets up a reaction which differs according to the mental and physical characteristics of the individual. The child who happens to be physically strong in proportion to his weight becomes a bully. The child of normal or reduced strength becomes introverted, has feelings of inadequacy and reacts accordingly. The obese child is judged according to size, not age, too much is expected of him both physically and mentally, wherefore the common but erroneous opinion that fat children are dull. As a matter of fact, most exceptional children are overweight but their mental precocity does not prevent them from forming faulty social adjustments, thus wasting or even perverting their superior mental ability. Most endocrinologists stoutly maintain that obesity is nearly always endogenous and must be treated with endocrine substances, while a majority of pediatricians hold

with the exogenous theory and claim that dietary restriction is the proper treatment. The equally good results reported by the two groups are difficult to reconcile but when their methods are examined it is discovered that most of those who profess to believe in the endocrine theory also include on their treatment a "moderate" reduction in diet and those who consider obesity to be entirely a matter of overconsumption of food often give a "little" thyroid or pituitary extract. The author sums up the evidence by pointing out that the fat child is metabolically different from the thin one. This difference seems to be constitutional and hereditary and may well be on an endocrine basis. The direct relationship of obesity to any endocrine gland has not been proved, nor has any adipogenic hormone been detected. The author proposes a carefully constructed diet, using endocrine substances as an adjuvant, realizing that their use is entirely empiric. The medication has considerable suggestive value and also keeps the child under observation much more closely than when diet alone is used. Exercise is not stressed, since it so increases appetite that the net effect is frequently nil. Fluid restriction and salt free diets affect only the water content of the body and have no effect on the adipose tissue itself.

Deuteroprotease in Treatment of Pneumonias. C. Brooks. New Orleans—p. 306.

**Treatment of Tularemia.**—Elson stresses the fact that there are three classes of tularemic inflammations of subcutaneous lymphatic nodes which are diagnosed and pass as other diseases. These inflammations are (1) cases that pass as glandular fevers, (2) inguinal adenitis (buboes) which remains undurated or only partially suppurating for a long time with out undergoing resolution and with marked constitutional symptoms and (3) the type of furunculosis that arises in the subcutaneous lymph nodes with or without subsequent suppuration. The fact that so many patients have no typical initial lesions does not exclude tularemic origin, as the mere contact with infected animals through handling, especially when the mucous membranes come in contact (well exemplified by tularemic conjunctivitis), suffices to cause localized or even in rare cases generalized tularemic infection. The author began to use syrup of ferrous iodide in the treatment of tularemia in 1932 and states that ferrous iodide is a specific.

**Radioactivity Five Years After Injection of Thorotrast**—Jacobson and Rosenbaum discuss the postmortem observations in a case in which 75 cc of thorotrast was injected intravenously five years before death. The ash of the liver preserved in 10 per cent neutral formaldehyde for six months showed that the liver still retained 27 per cent of the gamma ray activity of the thorotrast injected five years previous to death. Ninety cc of the formaldehyde in a sealed bottle did not show any radioactivity. The approximate gamma-ray activity of the liver ash was 0.3 microgram of radium. It is considered that the changes observed at necropsy were due to the longstanding presence of thorium or its disintegration products and that the amount of radioactive substance present was sufficient to induce the fibrotic changes seen in the liver, spleen and lymph nodes.

**Roentgen Treatment of Gas-Forming Infections**—Since August 1928, Kelly and his collaborators have collected data in 143 cases of gas gangrene infection treated with x-rays. A definite amount of x-rays to cover all cases can never be stated, as each case is a distinct clinical problem. Any one with a working knowledge of radiation therapy should be able to treat a case if he is not compelled to start too late. The thicker the part the higher the voltage and the more filtration is indicated, but since it is necessary to treat over a period of only three days or at the longest five days, making the number of treatments vary from six to ten, no complications should arise from the use of 100 roentgens per port at one treatment if the correct voltage and filtration are used. If treatment extends beyond the third day, unless new areas are being treated 50 roentgens per port might be sufficient. An increase in filter would also add to the protection of the patient. Since 1931 no patient who has been thus treated has died of gas gangrene. The lowered mortality and the number of recoveries in the non-amputation group and in the no-serum group proved beyond question that the use of x-rays in treating gas gangrene approaches the action of a specific. There are no contraindications to their use by a qualified radiologist. Severe debridement measures are no longer justifiable. In addition to lowering mortality the authors are certain that many arms and legs have been saved. A low mortality rate is no longer the sole standard of successful treatment of gas gangrene if it has been obtained at the sacrifice of amputation. Some patients treated early in the disease recovered following two or three roentgen treatments. If patients are treated early, during the first twenty-four hours of the disease, there should be a 100 per cent recovery. By use of the roentgenogram a diagnosis of gas gangrene can be made early, with the first accumulation of gas in the deep tissues. This method of examination is essential in all cases of suspected gas gangrene. Prophylactic use of x-rays is advised in all suspected cases, in fact, in all types of injuries such as those in which gas gangrene infections commonly develop. Patients complaining of an unusual amount of pain following a hypodermic injection might well be roentgenographed for gas in the deeper tissues as this infection following

hypodermic injection has been reported in the literature. X-rays have also been of benefit in treating arteriosclerotic and diabetic patients in whom gas gangrene has developed. The use of serum is not absolutely essential to recovery and its use should be conservative with avoidance of serum sickness, which only adds to the patient's illness. Tetanus serum must be given. Some filter and adequate kilovoltage to penetrate the involved part must be used. Up to this time no patient has died of gas gangrene who has received a treatment in the morning and a treatment in the evening for three days over all the involved area.

**Dextrose Utilization in Surgical Patients**—Twenty six male patients who had undergone surgical procedures and one patient undergoing preparation for surgery were followed over a period of from two to ten days, during which time Winslow carefully checked the amount and rate at which fluids were administered intravenously. He recommends the routine use of 5 per cent dextrose in distilled water for patients who require water and some carbohydrate parenterally, either in preparation for or following an operation. The solution is isotonic with blood. Its dextrose content is sufficient to prevent ketosis and to provide ideal fuel for energy. It protects the liver and avoids the edema which may result from the promiscuous use of physiologic solution of sodium chloride. No serious complications such as dehydration, diuresis, unusual loss or retention of fluids which might be ascribed to the dextrose solution were observed when 3 liters was administered daily at rates of from 300 to 500 cc an hour. This is an inadequate daily caloric intake but this is not an important objection in patients with fair general nutrition or in those who will be taking food orally in a few days. About 98 per cent of the dextrose is utilized when administered at the rate of from 300 to 500 cc an hour, averaging 0.35 Gm of dextrose hourly per kilogram of body weight. A 10 per cent dextrose solution in distilled water is hypertonic with blood is mildly diuretic and can be given at the same rates of administration as 5 per cent dextrose without harmful effects supplying the patient with 93 per cent more carbohydrate than an equal volume of 5 per cent dextrose solution. In this study 95 per cent of the administered dextrose (10 per cent solution) was utilized, making this solution the

author's choice in the presence of hepatic damage, thyroid crisis, inanition and cachexia. Although no measurable damage was observed when 500 cc an hour of the solution was administered, from 200 to 300 cc of the 10 per cent solution hourly is preferred to larger amounts.

**Detection of Hidden Abscesses**—Strauss and his colleagues report a method for the detection of hidden abscesses in patients who are going through a septic course. They detect such abscesses by the use of substances emitting gamma rays which, when injected intravenously, are accumulated in the abscessed area and, as the result of this radioactivity, are observed with a sensitive electron counter. The counter tube which is generally referred to as a Geiger-Muller tube is essentially a gas-filled diode consisting of a hollow cylindrical conductor (the cathode) mounted axially about a central conducting filament (the anode). Under the influence of an external source of penetrating radiation the counter tube mechanism initiates a process of "collision ionization" that produces a discharge through the gas between the cathode and the anode. The counter tube is so surrounded with lead metal that it is shielded for all practical purposes against gamma rays except for those entering through a small opening over which different regions of the dog were placed and counts taken. Thorium dioxide was injected either intravenously or intra-arterially on the affected side (following the technique used by Sedgwick and Solotuchin) in dogs having abscesses of the thigh created by the subcutaneous injection of a suspension of staphylococcus, streptococcus or *Bacillus coli* in intrascapular earth. The procedure was as follows. In the late afternoon the abscess was produced. The next morning the animal was injected intra-arterially on the affected side with 5 cc of colloidal thorium dioxide. During the afternoon the animal was anesthetized and the dog was passed over the tube of the counter. Determinations of five minutes duration were made over various regions of the body. Frequent basal counts were done and the head, the upper and lower parts of the chest, the abdomen and the thigh were examined. At least three determinations were made over each of the foregoing regions and the results were averaged. In five of seven experiments the count over the abscessed area was from one to four impulses a minute higher than the basal count. In three of these experiments this count was higher than in any other region of the body. In the other two dogs the count over the chest was higher than over the abscess itself. In these instances the thorium in the liver or in a large arterial trunk was perhaps sending gamma rays into the receiving tube. The authors conclude that the localization of an abscess often may be a life saving procedure and that their results seem encouraging and that the use of compounds with artificially induced radioactivity, much more potent than thorium dioxide, should increase the number of gamma rays from even a small focus and a low concentration of the radioactive material in it.

### Thyrotoxicosis Following Thyroidectomy—Fulton:

his associates reviewed the histories of thirty-nine patients with persistent or recurrent symptoms of thyrotoxicosis after a total thyroidectomy. Since 1923 when the preoperative use of iodine began these thirty-nine patients have continued to be thyrotoxic or it has redeveloped following thyroidectomy. Fourteen of these thirty-nine patients were free from symptoms for a period of less than six months following their first operation; persistent thyrotoxicosis. In contrast to them in twenty-five cases the duration of freedom from symptoms following operation was more than six months, the average being 1.5 years; recurrent thyrotoxicosis. As a basis for comparison twenty-five patients who had been followed in the endocrine clinic for an average period of seven years and had not had a recurrence of thyrotoxicosis during this interval are used. There were no striking differences between the three groups. Two points of difference are that the patients in whom recurrent developed or thyrotoxicosis persisted were on the average somewhat younger and had somewhat larger goiters than the control group. Their initial symptoms, however, were not so long standing; their average basal metabolism was not impressively high and their response to rest in bed and iodine as measured by the drop in cardiac rate and metabolism compared favorably with that seen in the control series. The author's observations at second operations indicate that continuance of recurrence of symptoms is associated in most instances, though not in all, with an appreciable amount of regeneration of thyroid tissue. What causes this active regrowth of gland is at present unknown. The clinical as well as the laboratory signs of thyrotoxicosis were as a rule less marked during the recurrent and persistent phases of the disease than when the patients were first seen. The return of symptoms was frequently associated with an increase in the degree of exophthalmos. In contrast to this are those patients in whom other features of hyperthyroidism have been relieved following operation, while exophthalmos has actually progressed to a marked degree. This may occur even with the development of postoperative myxedema. These facts emphasize the dissociation that may exist between exophthalmos and many of the other features of toxic goiter. The author's treatment of choice for both the recurrent and the persistent cases has been a second thyroidectomy. The majority of patients have been relieved of symptoms by this procedure and have remained well over an average period of six years. In a few instances roentgen therapy or prolonged iodine administration has satisfactorily controlled symptoms either in place of a second operation or subsequent to it. In three patients a third operation and in two others a fourth operation has been necessary.

**Value of Splenectomy**—In evaluating the efficacy of splenectomy, Collins studied the outcome of the eighty-one splenectomies performed between July 1928 and October 1938 at the Los Angeles County General Hospital. He finds that splenectomy is the only proper treatment for traumatic rupture of the spleen, as soon as the patient's condition permits. Elective splenectomy has its greatest usefulness in instances of essential chronic thrombopenic purpura and congenital hemolytic icterus. Its value in early Banti's syndrome is less clearly defined and the postoperative morbidity in this disease is a formidable factor. Elective splenectomy in certain other diseases such as sickle cell anemia, Gaucher's disease, malaria and early portal cirrhosis with splenomegaly, is not usually advisable. Each individual case must be carefully evaluated. Splenectomy is usually contraindicated in polycythemia vera, syphilis, Hodgkin's disease, tuberculosis, the leukemias or radiosensitive splenomegalies.

**Radiotherapy in Nonmalignant Uterine Hemorrhage**—Windeyer believes that roentgen or radium therapy is the treatment of choice in nonmalignant irregular hemorrhage at or near the menopause. Of the sixty-one consecutive cases of menopausal menorrhagia that he has treated success was obtained in fifty-seven, partial success in one, one was unsuccessful and two were untraced. Radium has been used almost exclusively and complications (discharge, nausea and vomiting) have all been due to radium insertion. Such complications have not been reported after the use of x-rays alone, and the production of amenorrhea has been just as certain. Therefore when both methods are available x-rays are to be preferred. In bleeding associated with fibroids occurring in women about or more than 40 years of age, x-rays seem to be more definitely indicated to radium because the distortion due to the tumor may cause the ovaries to lie at an increased distance from the endometrium, with consequent diminution of the dose received from the intra-uterine radium. Radiotherapy should not be used in the treatment of fibroids in young women unless there is some factor, such as cardiac disease, which makes the risk of surgery too great. In menorrhagia in young women, if one accepts the action of radium as being mainly on the ovary and it appears that this is the only way that the greater difficulty in sterilizing young women can be explained, it would seem advisable to use x-rays rather than radium. The dose to the ovaries can be assessed with greater accuracy and there is less damage to the endometrium, with consequently a greater chance that an impregnated ovum can be retained.

**Aplastic Anemia with Recovery**—Boon reports a case showing diminution in all the cellular elements of the blood following arsphenamine therapy. Fortunately the anemia due to aplasia in this case was not increased by hemorrhage from the mucous membranes, as occurred in a recent case of aplastic anemia due to gold therapy for rheumatoid arthritis in which a fatal hematemeses followed. Despite a fall to 18 per cent hemoglobin and 750,000 red cells recovery has occurred, and the patient is apparently well more than two years after the last transfusion. During the period that the blood level was kept up by transfusions there was no evidence of spontaneous recovery, the hemoglobin always being about 40 per cent immediately before and 50 per cent immediately after a transfusion. Within a few weeks of ceasing transfusions there was an increase of reticulocytes and a gradual rise of red cells. The color index remained high until a normal level was reached, and granulocytes lagged behind in their recovery. There seems no doubt that without repeated transfusions the case reported would have proved fatal. In all 12,540 cc of blood was given as twenty-five transfusions.

**Therapeutic Use of Barbiturates**—Clark summarizes the chief clinical uses of the barbiturates as follows: (1) cerebral sedatives (in epilepsy, seasickness and the like), (2) hypnotics, (3) narcotics (to lessen the pain of childbirth), (4) basal nar-

cotics and (5) anesthetics. Many of the distinctions drawn between the actions of barbiturates and the actions of other hypnotics depend on the fact that barbiturates such as barbital and phenobarbital produce a more prolonged effect than do most other hypnotics. The potency of barbiturates varies within a relatively small range. The duration of action of the hypnotics depends chiefly on the rate at which they are broken down in the body. Barbital is an exceptional compound in the general class of barbiturates, because the body is unable to break it down and it is excreted unchanged in the urine. Consequently it is removed from the body extremely slowly. The more complex and less stable barbiturates are broken down by the body, probably by the liver, and only small quantities are excreted in the urine. The duration of the action of barbiturates other than barbital depends therefore not on their rate of excretion but on the rate of their destruction in the body, and this varies greatly in different cases. Half destruction of phenobarbital occurs in from six to twelve hours. The safety of barbiturates depends on the therapeutic range, i.e. the ratio between the dose likely to produce the required action and the maximal dose that is unlikely to produce toxic effects, the change of unusual undesirable effects and the chance of cumulation. The estimation of the therapeutic range is rendered difficult by the fact that extensive individual variation occurs in the response to barbiturates, as indeed it does in the response to all other drugs. As a general rule the quick-acting barbiturates are safer than the long-acting ones, because with the former cumulation is less likely and, moreover, any toxic effects, if produced, are of shorter duration. The long-acting barbiturates find their chief employment in the use of phenobarbital in epilepsy and of barbital and phenobarbital as hypnotics. It seems probable that the shorter-acting barbiturates such as pentobarbital sodium are preferable to barbital as hypnotics. Barbiturates with a shorter action than phenobarbital might be found equally efficacious in epilepsy and would be less liable to produce undesirable side actions such as rashes. Barbiturates appear to be satisfactory agents for the production of preoperative narcosis provided only a slight degree of narcosis is produced. The production of narcosis deep enough to relieve severe pain appears to be unsatisfactory because of the incidence of delirium. The chief danger of full anesthesia by barbiturates is paralysis of the respiratory center. This paralysis is difficult to overcome. The permanence of this undesirable effect is surprising in view of the rapid rate of destruction of the drugs in the body.
